KEY TO PRONUNCIATION.

a as in fat, man, pang.
ā as in fate, mane, dale.
ä as in far, father, guard.
â as in fall, talk, naught.
à as in ask, fast, ant.
ã as in fare, hair, bear.

e as in met, pen, bless.

ū as in mute, acute, few (also new, tube, duty).
ù as in pull, book, could.
ü German ü, French u.

oi as in oil, joint, boy.
ou as in pound, proud, now.

A single dot under a vowel in an unaccented syllable indicates its abbreviation and lightening, without absolute loss of its distinctive quality. Thus:

ạ as in prelate, courage, captain.
ẹ as in ablegate, episcopal.
ọ as in abrogate, eulogy, democrat.
ụ as in singular, education.

A double dot under a vowel in an unaccented syllable indicates that, even in the mouths of the best speakers, its sound is variable to, and in ordinary utterance actually becomes, the short *u*-sound (of but, pun, etc.). Thus:

a̤ as in errant, republican.
e̤ as in prudent, difference.
i̤ as in charity, density.
o̤ as in valor, actor, idiot.

ä̤ as in Persia, peninsula.
ë̤ as in *the* book.
ṳ̈ as in nature, feature.

A mark (⌣) under the consonants *t, d, s, z* indicates that they in like manner are variable to *ch, j, sh, zh*. Thus:

t̰ as in nature, adventure.
d̰ as in arduous, education.
s̰ as in pressure.
z̰ as in seizure.

th as in thin.
ᴛʜ as in then.
ċh as in German ach, Scotch loch.
ṅ French nasalizing n, as in ton, en.
ly (in French words) French liquid (mouillé) l.
′ denotes a primary, ″ a secondary accent. (A secondary accent is not marked if at its regular interval of two syllables from the primary, or from another secondary.)

SIGNS.

‹ read *from;* i. e., derived from.
› read *whence;* i. e., from which is derived.
\+ read *and;* i. e., compounded with, *or* with suffix.
= read *cognate with;* i. e., etymologically parallel with.
√ read *root.*
* read *theoretical* or *alleged;* i. e., theoretically assumed, or asserted but unverified, form.
† read *obsolete.*
★ refers, in all cases, to material which will be found in the supplementary pages. It is used in the cross-references, and is also placed above (rarely below) the initial letter of a word, when an addition to its definitions will be found in the supplementary pages at the end of one or another of the various volumes.

SPECIAL EXPLANATIONS.

A superior figure placed after a title-word indicates that the word so marked is distinct etymologically from other words, following or preceding it, spelled in the same manner and marked with different numbers. Thus:

back[1] (bak), *n.* The posterior part, etc.
back[1] (bak), *a.* Lying or being behind, etc.
back[1] (bak), *v.* To furnish with a back, etc.
back[1] (bak), *adv.* Behind, etc.
back[2]† (bak), *n.* The earlier form of *bat*[2].
back[3] (bak), *n.* A large flat-bottomed boat, etc.

Various abbreviations have been used in the credits to the quotations, as "No." for *number*, "st." for *stanza*, "p." for *page*, "l." for *line*, ¶ for *paragraph*, "fol." for *folio*. The method used in indicating the subdivisions of books will be understood by reference to the following plan:

Section only	§ 5.
Chapter only	xiv.
Canto only	xiv.
Book only	iii.
Book and chapter	iii. 10.
Part and chapter	iii. 10.
Book and line	iii. 10.
Book and page	iii. 10.
Act and scene	iii. 10.
Chapter and verse	iii. 10.
No. and page	iii. 10.
Volume and page	II. 34.
Volume and chapter	IV. iv.
Part, book, and chapter	II. iv. 12.
Part, canto, and stanza	II. iv. 12.
Chapter and section or ¶	vii. § or ¶ 3.
Volume, part, and section or ¶	I. i. § or ¶ 6.
Book, chapter, and section or ¶	I. i. § or ¶ 6.

Different grammatical phases of the same word are grouped under one head, and distinguished by the Roman numerals I., II., III., etc. This applies to transitive and intransitive uses of the same verb, to adjectives used also as nouns, to nouns used also as adjectives, to adverbs used also as prepositions or conjunctions, etc.

The capitalizing and italicizing of certain or all of the words in a synonym-list indicates that the words so distinguished are discriminated in the text immediately following, or under the title referred to.

The figures by which the synonym-lists are sometimes divided indicate the senses or definitions with which they are connected.

The title-words begin with a small (lower-case) letter, or with a capital, according to usage. When usage differs, in this matter, with the different senses of a word, the abbreviations [*cap.*] for "capital" and [*l. c.*] for "lower-case" are used to indicate this variation.

The difference observed in regard to the capitalizing of the second element in zoölogical and botanical terms is in accordance with the existing usage in the two sciences. Thus, in zoölogy, in a scientific name consisting of two words the second of which is derived from a proper name, only the first would be capitalized. But a name of similar derivation in botany would have the second element also capitalized.

The names of zoölogical and botanical classes, orders, families, genera, etc., have been uniformly italicized, in accordance with the present usage of scientific writers.

simular (sim′ū-lär), *a.* and *n.* [Irreg. < L. *simulare*, make like, simulate, < *similis*, like: see *similar*. > There be three degrees of this hiding and veiling of a man's self: the first, closeness, reservation, and secrecy; . . . the second, dissimulation in the negative—when a man lets fall signs and arguments that he is not that he is: and the third, *simulation* in the affirmative—when a man industriously and expressly feigns and pretends to be that he is not.
> *Bacon*, Simulation and Dissimulation (ed. 1887).

The *simulation* of nature, as distinguished from the actual reproduction of nature, is the peculiar province of stage art. *Scribner's Mag.*, IV. 438.

2. Specifically—(*a*) In *phonology*, imitation in form; the alteration of the form of a word so as to approach or agree with that of another word having some accidental similarity, and to suggest a connection between them: a tendency of popular etymology. Examples are *frontispiece* for *frontispice* (simulating *piece*), *curtal-ax* for *cutlas* (simulating *ax*), *sovereign* for *soverain* or **soveren* (simulating *reign*), *sparrowgrass* for *asparagus* (simulating *sparrow* and *grass*), etc.

Simulation. The feigning a connection with words of similar sound is an important fact in English and other modern languages: asparagus > sparrow-grass. It probably had just as full play in ancient speech, but its effects cannot be so surely traced.
F. A. March, Anglo-Saxon Grammar, p. 28.

(*b*) In *biol.*, unconscious imitation or protective mimicry; assimilation in appearance.—**3.** Resemblance; similarity. [Rare.]

> M,—why, that begins my name . . . M, O, A, I; this *simulation* is not as the former; and yet, to crush this a little, it would bow to me, for every one of these letters are in my name. *Shak.*, T. N., ii. 5. 151.

4. In *French law*, a fictitious engagement, contract, or conveyance, made either as a fraud where no real transaction is intended, or as a mask or cover for a different transaction, in which case it may sometimes be made in good faith and valid.—**Syn. 1.** See *dissemble.*

Simulium (si-mū′li-um), *n.* [NL. (Latreille, 1802), < L. *simulare*, imitate, simulate: see *simulate.*] An important genus of biting gnats, typical of the family *Simuliidæ*. They are small humpbacked gnats, of a gray or blackish color, with broad pale wings. Many well-known species belong to this genus,

Their bite is very painful, and they sometimes swarm in such numbers as to become a pest. The larvæ and pupæ are aquatic, and generally live in shallow swift-running streams. Also *Simulia*. See cut under *turkey-gnat.*

sin[1] (sin), *n.* [< ME. *sinne, synne, sunne, senne, zenne*, < AS. *syn, synn* (in inflection *synn-, sinn-, senn-*) = OS. *sundea, sundia* = OFries. *sinne, sende* = MD. *sunde, sonde*, D. *zonde* = MLG. *sunde*, LG. *sunne, sunn* = OHG. *suntea, sunta, sundea, sunda*, MHG. *sunde, sünde*, G. *sünde*, = Icel. *syndh, synth*, later *synd*, = Sw. Dan. *synd* (not in Goth.), sin, akin to L. *son(t-)s*, sinful, guilty, *sonticus*, dangerous, hurtful, and perhaps to Gr. *ἄτη*, sin, mischief, harm. According to Curtius and others, the word is an abstract noun formed from the ppr. represented by L. **sen(t-)s, en(t-)s*, being, and by AS. *sōth*, true, sooth, = Icel. *sannr*, etc., lit. 'being (so)' (see *sooth*), Goth. *sunja*, the truth, sooth.] **1.** Any want of conformity unto or transgression of the law of God. (*Westminster Assembly's Shorter Catechism.*) The true definition of sin is a much contested question, theologians being broadly divided into two schools of thought, the one holding that all sin consists in the voluntary and conscious act of the individual, the other that it also includes the moral character and disposition of the race; one that all moral responsibility is individual, the other that there is also a moral responsibility of the race as a race. To these should be added a third school, which regards sin as simply an imperfection and immaturity, and therefore requiring for remedy principally a healthful development under favorable conditions. Theologians also divide sin into two classes, *actual sin* and *original sin.* Actual sin consists in the voluntary conscious act of the individual. (See *actual.*) Original sin is the innate depravity and corruption of the nature common to all mankind. But whether this native depravity is properly called *sin*, or whether it is only a tendency to sin and becomes sin only when it is yielded to by the conscious voluntary act of the individual, is a question upon which theologians differ. Roman Catholic and other theologians, following the early church fathers, distinguish between *mortal* (or *deadly*) and *venial* sins. Mortal or deadly sins are such as wilfully violate the divine law, destroy the friendship of God, and cause the death of the soul. The seven mortal or deadly sins are pride, covetousness, lust, anger, gluttony, envy, and sloth. Venial sins are such transgressions as are due to inadvertence, do not destroy the friendship of God, and, while tending to become mortal, are not in themselves the death of the soul. The difference is one of degree, not of kind.

> And ye knowe also that it was do be me, and so sholde myn be the *synne*. *Merlin* (E. E. T. S.), i. 80.
>
> Sure, it is no *sin;*
> Or of the deadly seven it is the least.
> *Shak.*, M. for M., iii. 1. 111.

At the court of assistants one Hugh Bewett was banished for holding publicly and maintaining that he was free from original *sin* and from actual also for half a year before. *Winthrop*, Hist. New England, II. 22.

Original *sin* is the product of human will as yet unindividualized in Adam, while actual *sin* is the product of human will as individualized in his posterity.

=**Syn. 3.** *Because, Since, As, Inasmuch as, For.* *Because* (originally *by cause*) is strong and the most direct. *Since*, starting from the idea of mere sequence in time, is naturally less emphatic as to causation: its clause more often precedes the main proposition. *As* is still weaker, and, like *since*, generally brings in the reason before the main proposition: *as* or *since* the mountain will not come to Mohammed, Mohammed must go to the mountain. *Inasmuch as* is the most formal and emphatic, being used only to mark the express reason or condition. *For* follows the main proposition, and generally introduces that which is really continuative of the main proposition and of equal or nearly equal importance, the idea of giving a reason being subordinate.

2. In *trigon.*, formerly, with reference to any arc of a circle, the line drawn from one extremity of the arc at right angles to the diameter which passes through its other extremity; now ordinarily, with reference not to the arc but to the angle which it subtends at the center of the circle, the ratio of the aforesaid line to the radius of the circle. Thus, in the diagram, BE is the sine of the arc AB (sometimes it is defined as half the chord of double the arc), and the ratio of BE to CB is the sine of the angle ACB. (See *trigonometrical functions*, under *trigonometrical*.) A more scientific definition of the sine is that of Euler, $\sin x = \frac{1}{2i}(e^{-xi} - e^{xi})$, where $i^2 = -1$, and e is the Napierian base. The sine is also fully defined by the infinite series

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \cdots$$

But all the properties of sines are readily deduced from the definition that the sine is such a function that it vanishes with the variable, while

$$\frac{d \sin x}{dx} = \sqrt{1 - (\sin x)^2}.$$

Abbreviated *sin*, as in formulæ here given.—**Arithmetic of sines**, analytical trigonometry. Its object is to exhibit the relation of the sines, cosines, tangents, etc., of arcs, multiple arcs, etc.—**Artificial sine.** See *artificial*.—**Coversed sine**, the versed sine of the complement of an angle. $$\frac{x^{m-1}}{(m-1)!} \pm \frac{x^{2m-1}}{(2m-1)!} + \frac{x^{3m-1}}{(3m-1)!} \pm \cdots$$

These functions were invented by Wronski.—**Sine of three lines which meet in a point**, the sine of the angle between the first line and the plane of the other two, multiplied by the sine of the angle between the other two lines.—**Sine of three planes**, the sine of the angle between the first plane and the intersection of the other two, multiplied by the sine of the angle between the other two planes.—**Subversed sine.** Same as *supplemental versed sine*.—**Supplemental versed sine**, the difference between the versed sine and the diameter.—**Versed sine**, unity minus the cosine. Formerly, for the arc AB (see the diagram), it was understood to be the line EA; now the ratio of EA to BC is the versed sine of the angle ACB.—**Whole sine of a circle**, the radius.

sin-eater† (sin'ē″tėr), *n.* Formerly, in some parts of England, one who was hired in connection with funeral rites to eat a piece of bread placed near the bier, and who by this symbol took upon himself the sins of the deceased, that the departed soul might rest in peace. The usage is said to have originated in a mistaken interpretation of Hosea iv. 8: "They eat up the sin of my people."

The manner [in the County of Hereford] was that, when the Corps was brought out of the house and layd on the Biere, a Loafe of bread was brought out, and delivered to the *Sinne-eater* over the corps, as also a Mazar-bowle of maple (Gossips bowle) full of beer, wch he was to drinke up, and sixpence in money, in consideration whereof he tooke upon him (ipso facto) all the Sinnes of the Defunct, and freed him (or her) from walking after they were dead.

3. In *math.*, an exceptional element or character of a continuum. (*a*) In *geom.*, a projective character of a locus consisting in certain points, lines, or planes being exceptional in their relations to it. (For examples, see *binode*.) An ordinary singularity is one of a set of singularities of which all others are modifications or compounds. Thus, an actual node upon a skew curve is a modification of an apparent node, and ought not to be reckoned as an ordinary singularity. But cusps and inflections, as stationary points and tangents, are ordinary singularities. A higher singularity is one which differs indefinitely little from an aggregation of ordinary singularities. (See *tacnode*.) By an ellipsis common in geometrical language, the word *singularity* is used for *point singularity*, or a relation to some exceptional point. Thus, a plane curve with neither nodes nor cusps is said to be without singularities, although, unless a conic, it has inflections, and unless a conic or cubic, double tangents. The word *singularity* is also used to denote the number of singular points, lines, or planes of any one kind; also for any number characteristic of a projective property, in which sense the order, class, and rank of a locus are sometimes termed *singularities*. (*b*) In the *theory of functions*, a property of a function consisting in it or its differential coefficient becoming discontinuous for a certain value or connected system of values of the variable.—**Elliptic, essential, hyperbolic singularity.** See the adjectives.—**Simple singularity**, a singularity of a function consisting in it or its differential coefficient becoming ambiguous or discontinuous at an isolated point or points, while remaining unambiguous and continuous at all other points sufficiently near to these. = Syn. 1. siphon (sī'fon), *n.* [Also *syphon*; < F. *siphon* = Sp. *sifón* = Pg. *siphão* = It. *sifone*, < L. *sipho*(*n*-), perhaps < Gr. *σίφων*, a tube, pipe, siphon; akin to *σιφλός*, hollow.] 1. A bent pipe or tube with legs of unequal length, used for drawing liquid out of a vessel by causing it to rise in the tube over the rim or top. For this purpose the shorter leg is inserted in the liquid, and the air is exhausted by being drawn through the longer leg. The liquid then rises by the pressure of the atmosphere and fills the tube, and the flow begins from the lower end. Sometimes an exhausting-tube (*a* in the figure) is placed on the longer leg; the air, in that case, is sucked out through *a* till the tube is filled to the cock *b*, which is then opened, and the flow commences—the cock *b* being so constructed as to close the suction-tube when the siphon is running. But the more general method is to fill the tube in the first place with the liquid, and then, stopping the mouth of the longer leg, to insert the shorter leg in the vessel; upon removal of the stop, the liquid will immediately begin to run. The flow depends upon the difference in vertical height of the two columns of the liquid, measured respectively from the bend of the tube to the level of the water in the vessel and to the open end of the tube. The flow ceases as soon as, by the lowering of the level in the vessel, these columns become of equal height, or when this level descends to the end of the shorter leg. The atmospheric pressure is essential to support the column of liquid from the vessel up to the top of the bend of the tube, and this height is consequently limited, varying inversely with the density of the liquid. At sea-level the maximum height is a little less than 30 inches for mercury and 34 feet for water.

In *Teredo* the united siphons are so long that the mollusk resembles a worm. See cuts under *ship-worm*, *Teredo*, *quahog*, and *Mya*[1]. (2) A similar siphon in some gastropods, extending from the anterior portion of the mantle over the head. See cut under *Siphonostomata*, 2. See *siphuncle*. (4) A tubular or canaliculate formation of the shell of any mollusk which covers or protects the soft siphon; especially, the siphuncle of a cephalopod, or the communication between the compartments of the shell. with holes equidistantly arranged in a circle, which can be revolved over a jet of compressed air or steam so as to produce periodic puffs. When the revolutions are rapid enough, the puffs coalesce into a musical tone. The revolution of the disk is effected either by a motor of some kind, or by setting the holes at an oblique angle so that the impact of the jet shall do the work. In the more complicated forms of the instrument two or more tones can be produced at once, either by having two or more concentric circles of holes in the same disk, or by two separate disks: the latter form is called a *double siren*. The number of revolutions required to produce a given tone can be counted and exhibited in various ways; and the application of the instrument in acoustical experiments and demonstrations is wide. In the cut *a* is a perforated disk made to revolve by the pressure of the air forced from the bellows beneath through *d*; *b*, vertical shaft revolving with the disk, and, by means of a pair of cog-wheels in the box *c*, turning the two index-hands on their respective dial-plates, and thus registering the number of revolutions made during the time of observation. Very large sirens are sometimes made for use as fog-signals, the sound being conveyed seaward in a large trumpet-shaped tube called a *fog-horn*, a name also given to the whole arrangement. See *fog-horn*. Also *sirene*.

American Manatee (*Trichechus manatus*), one of the *Sirenia*.

The brain is small and particularly narrow. The periotic and tympanic bones are ankylosed together, but not with the squamosal; the foramen magnum is posterior, directed somewhat downward; the lower jaw has a well-developed ascending ramus, a coronoid process, and an ordinary transverse condyle; and the teeth are molariform, adapted to chew herbage. The neck is moderate, and the axis has an odontoid process. The fore limbs are moderately developed, with a flexure at the elbow; the carpal, metacarpal, and phalangeal bones are directly articulated and of normal number. There are two mammæ, pectoral. The heart is deeply fissured between the ventricles. (See first cut under *heart*.) In nearly all the above characters the *Sirenia* are contrasted with the *Cetacea*, which they resemble, and with which they were formerly classed as *Cetacea herbivora*. They are large or huge unwieldy and ungainly aquatic animals, inhabiting the sea-shores, bays, and estuaries of various countries, never going out to sea like cetaceans, nor ascending rivers far. They feed entirely on aquatic vegetation. There are only two living genera, *Trichechus* and *Halicore*, the manatees and dugongs, representing two families, *Trichechidæ* and *Halicoridæ*. The sea-cow, *Rhytina stelleri*, recently extinct, represents a third family, *Rhytinidæ*. There are several other extinct genera, some of them constituting the family *Halitheriidæ*. sirgang (sėr'gang), *n.* [E. Ind.] The so-called green jackdaw of Asia, *Cissa sinensis*. The sirgang inhabits the southeastern Himalayan region, and thence through Burma to Tenasserim, and has occasioned much literature. It was originally described and figured by French ornithologists as a roller, whence its earliest technical name, *Coracias chinensis* of Boddaert (1783), with the English synonym *Chinese roller* of Latham. These terms being overlooked, the bird was renamed *Corvus speciosus* by Shaw, and the genus *Cissa* (later spelled *Kitta*) was founded upon it by Boie in 1826, since which time it has mostly been called *Cissa sinensis*, sometimes *C. speciosa*. It is 15½ inches long, the wing 6, the tail 7 to 8½; the head is fully crested; the bill and feet are coral-red. The fresh-molted plumage in life is a lovely green, but has the peculiarity of soon changing to verdigris-blue, as it does also in stuffed specimens, particularly if exposed to the light. This green or blue is varied with a black fillet encircling the head, with white tips and black subterminal bars on the tail-feathers and inner quill-feathers, and with bright sanguine red on the wings, which easily fades to a dull reddish-brown. A variety of the sirgang found in Sumatra is called *C. minor*; other species of the same genus are the ★Ceylonese *C. ornata* and the Japanese *C. thalassina*.

2. Sisters collectively, or a society of sisters; in religious usage, an association of women who are bound by monastic vows or are otherwise devoted to religious work as a vocation. In the Roman Catholic Church the members of a sisterhood may be bound by the irrevocable vows of poverty, chastity, and obedience, and are then called *nuns*, or may be merely under one rule and bound by revocable vows. In the Church of England and its offshoots there are also sisterhoods, the members of which either take a revocable vow of obedience to the rule of their association, or live under the rule of the order without vow. Among the more important of the sisterhoods are the Sisters of Charity (see *charity*), the School Sisters of Notre Dame, the Little Sisters of the Poor, the Sisters of the Assumption, the Congregation of Sisters of Notre Dame, the Anglican Sisterhoods of St. John the Baptist, of the Holy Communion, of St. Mary, etc. The Sisters of Mercy is an order founded in 1827 in Dublin, with purposes analogous to those of the Sisters of Charity. The vows are for life. A similar sisterhood in the Church of England was founded about 1845 for assisting the poor. It consists of three orders—those who live in community actively engaged in assisting the poor, those who live in community but are engaged in devotions and other secluded occupations, and those not living in the community but assisting it as co-workers. There are also a number of somewhat similar organizations in the Episcopal Church in the United States.

Sisymbrieæ (sis-im-brī'ē-ē), *n. pl.* [NL. (Endlicher, 1836), < *Sisymbrium* + *-eæ*.] A tribe of plants, of the family *Brassicaceæ*, originally including 16 genera, of which *Sisymbrium* was the type. In the system of Bentham and Hooker it included 22 genera. In that of Engler and Prantl it is not recognized but is substantially equivalent to the subtribe *Sisymbriinæ* in the tribe *Sinapeæ*, though some of the most important genera are placed in other tribes.

Sisymbrium (si-sim'bri-um), *n.* [NL. (Tournefort, 1700), < Gr. σισύμβριον, a name applied to certain odorous plants, one said to be a crucifer, another *Mentha aquatica*.] A genus of cruciferous plants, type of the tribe *Sinapeæ*. It is characterized by annual or biennial smooth or hairy stems; flowers with free and unappendaged stamens, and a roundish and obtuse or slightly two-lobed stigma; and linear sessile pods, usually with three-nerved valves and many oblong seeds with straight cotyledons. It is destitute of the two-parted bristles found in the related genus *Erysimum*, which also differs in its linear or oblong leaves. Besides a great number of doubtful species, about 50 are recognized as distinct. They are natives especially of central and southern Europe, Siberia, and western Asia as far as India; a few are found in temperate and subarctic North America, and a very few in the southern hemisphere. They bear a stellate cluster of radical leaves, and numerous alternate stem-leaves which are usually clasping and irregularly lobed or pinnately divided. The flowers are usually borne in a loose bractless raceme, and are commonly yellow. The various species simulate the habit of many widely different genera. A few have white, pink, or purplish flowers. For *S. officinale*, see *hedge-mustard* (sometimes used also for any plant of the genus); and for *S. Irio*, see *London-rocket*. Several species formerly regarded as belonging to *Sisymbrium* are now referred to other genera, as the tansy-mustard of the southern United States, *Sophia pinnata*, and the mouse-ear cress of Europe, *Stenophragma Thaliana*, naturalized in the United States, also the hedge-garlic, *Alliaria Alliaria*, in waste places from Ontario to Virginia.

Sisyphean (sis-i-fē'an), *a.* [< Gr. Σισύφειος, also Σισύφιος, pertaining to Sisyphus, < Σίσυφος (supposed to be connected with σοφός), L. *Sisyphus*, (see def.).] Relating or pertaining to Sisyphus, in Greek mythology, a king of Corinth, whose punishment in Tartarus for his crimes consisted in rolling a huge stone to the top of a hill, whence it constantly rolled down again, thus rendering his labor incessant; hence, recurring unceasingly: as, to engage in a *Sisyphean* task.

Sisyrinchieæ (sis#i-ring-kī'ē-ē), *n. pl.* [NL. (Klatt, 1866), < *Sisyrinchium* + *-eæ*.] A tribe of monocotyledonous plants of the family *Iridaceæ*. It is characterized by commonly terminal or peduncled spathes, by concave or keeled bracts within the spathe and opposite to the two or more usually pedicelled flowers, and by style-branches alternate with the anthers or borne on a style which is longer than the stamens. As restricted by Engler it includes seven genera, classed in two subtribes, the *Libertinæ* and the *Sisyrinchinæ*. The first includes four genera, of which *Belamcanda*, the blackberry-lily, is the best known. Of the other subtribe *Sisyrinchium* is the type as well as of the tribe. They are mostly delicate grass-like herbs native to temperate or subtropical countries of both hemispheres. See *Sisyrinchium*, *blackberry-lily* (under *lily*), and *leopard-flower*.

Sisyrinchium (sis-i-ring'ki-um), *n.* [NL. (Tournefort, 1700), transferred by Linnæus from the iris; < Gr. σισυρίγχιον, a bulbous plant, said to have been of the iris family.] A genus of monocotyledonous plants of the family *Iridaceæ*, type of the tribe *Sisyrinchieæ*. It is characterized by round or two-edged stems without a bulbous base, rising from a cluster of thickened fibers; flowers with the filaments commonly partly united into a tube, and with three slender undivided style-branches; and a globose ovary which becomes an exserted capsule in fruit. There are about 120 species, nearly all American, occurring both in the tropical and in the temperate zones, one species also indigenous in Ireland. They are tufted plants with numerous flat, long, and narrow upright leaves which are all or mostly radical, and usually a single spathe with numerous open flattish flowers. Nearly all the species of the eastern United States are known as *blue-eyed grass*, from the flowers. See *rush-lily*.

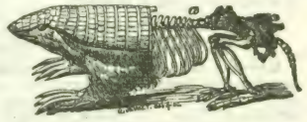
More specifically—(*a*) The test, shell, lorica, or set of spicules of any protozoan, as an infusorian, radiolarian, foraminifer, or other animalcule, exhibiting the utmost diversity of form, structure, and substance. See cuts under *Foraminifera, Infusoria,* and *Radiolaria.* (*b*) In sponges, the whole sponge except the animalcules which fabricate it. (See cut under *Porifera.*) A bath-sponge, for example, is only the skeleton, from which the animals have been decomposed and displaced. This skeleton presents itself in three principal textures, the fibrous, chalky, and glassy. In a few cases it is gelatinous. (See *Fibrospongiæ, Calcispongiæ, Silicispongiæ, Myxospongiæ.*) A nearly constant and very characteristic feature of sponge-skeletons is the presence of calcareous or silicious spicules. (See *spicule.*) Spicules in excess of fibrous tissue, and especially when consolidated in a kind of network, form the glass-sponges, some forms of which are very beautiful. (See cut under *Euplectella.*) Certain minute scleres of some sponges are flesh-spicules, and belong to the individual sponge-animalcules rather than to the general sponge-tissue. (Compare *microsclere* with *megasclere.*) (*c*) The special or general hard parts of echinoderms, as the shell of a sea-urchin with its spines and oral armature; the spicules or scleres in the integument of a holothurian; the rigid parts of starfishes, crinoids, and the like. fishes the whole skeleton is cartilaginous. In most vertebrates, however, the cartilage forming the skeleton of the embryo or fetus is mainly converted into bone by the process of ossification, or deposition of bone-earth, some parts, especially of the ribs, remaining as a rule cartilaginous. The vertebrate endoskeleton consists of axial parts, the *axial skeleton,* in a series of consecutive segments, the vertebræ, with their immediate offshoots, as ribs, and at the head end a skull or cranium (except in the *Acrania* or lowest fishes); and of appendages, the *appendicular skeleton,* represented by the one or two (never more) pairs of limbs, if any, including the pectoral and pelvic arch, or shoulder- and hip-girdle, by means of which the limbs are attached to the axis or trunk. Various other ossifications may be and usually are developed in



tendinous or ligamentous tissue, or in viscera, and constitute the *scleroskeleton* or *splanchnoskeleton*. Teeth are certainly skeletal parts, though not usually counted with

the bones of the skeleton; they are horny, not osseous or dentinal, in some animals. (2) The external covering of the body; the cuticle or epidermis; the dermo-skeleton or exo-skeleton, including all the non-vascular, non-nervous cuticular or epidermal structures, as horns, hoofs, claws, nails, hairs, feathers, scales, etc. In man the exoskeleton is very slight, consisting only of cuticle, nails, and hair; but in many vertebrates it is highly developed and may be bony, as in the shells of armadillos and of turtles, the plates, shields, or bucklers of various reptiles and fishes, etc. See also cuts under *archipterygium*, *carapace*, *Catarrhina*, *elasmosaur*, *Elephantinæ*, *endoskeleton*, *epipleura*, *Equidæ*, *fish*, *Ichthyornis*, *Ichthyosauria*, *Ichthyosaurus*, *Mastodontinæ*, *Mylodon*, *ox*, *Plesiosaurus*, *pterodactyl*, and *Pteropodidæ*; also cuts under *skull*, and others there named.

A skull is possessed by all vertebrates excepting the lancelets, and by no other animals. It is sometimes divided into the skull proper, cranium in strictness or brain-box, and the facial region or face. In the adult human skull eight cranial and fourteen facial bones are commonly enumerated, though the real number of osseous elements is much larger. The eight cranial bones are the occipital, two parietal, two temporal, frontal, sphenoid, and ethmoid. The fourteen facial bones are two nasals, two lacrymals, two superior maxillaries, two malars, two palatals, two inferior turbinals, one inferior maxillary, and one vomer. This enumeration of the bones is exclusive of the bonelets of the ear, which, however, are counted in vertebrates below mammals. Of these bones, the mandible, vomer, and frontal are really paired, or of lateral halves; the supramaxillary, ethmoid, sphenoid, occipital, and temporal are compound bones of several separate centers of ossification; the rest are simple. The most composite bone is the temporal, whose ankylosed stylohyoid process (peculiar to man) is an element of the hyoid arch. A skull of similar construction characterizes mammals at large, though its figure is usually quite different (owing mainly to production of the facial and reduction of the cranial parts), and though some of the bones which are confluent in man may remain distinct. In birds the skull is characterized by the great size of the cranial bones in comparison with that of the facial bones (excepting the specially enlarged intermaxillary and inframaxillary), the extensive and complete ankyloses of cranial bones, the permanent and perfect distinctness of pterygoid

B. Base of Human Skull, right half, outside, under surface: *bo*, basioccipital, or basilar process; *c*, occipital condyle; *e*, entrance to Eustachian tube, reference-line *e* crossing foramen lacerum medium, between which and *e* and 5 is petrous part of temporal bone; *g*, glenoid fossa of temporal bone, for articulation of lower jaw; *m*, mastoid process; *n*, posterior nares; *pt*, pterygoid fossa; *so*, supra-occipital; *st*, styloid process; *z*, malar bone, joining zygomatic process of squamosal to form zygomatic arch or zygoma; 1, 2, anterior and posterior palatine foramen; 3, points in front of foramen lacerum medium; 4, foramen ovale; 5, carotid canal; 6, stylomastoid foramen; 7, foramen lacerum posterius, or jugular foramen.

C. Base of Human Skull, left side, interior or cerebral surface: *a*, alisphenoid, or greater wing of sphenoid; *bo*, basioccipital, or basilar process of occipital; *c*, cribriform plate of ethmoid; *f*, orbital plate of frontal; *g*, crista galli; *o*, orbitosphenoid, or lesser wing of sphenoid; *p*, pituitary fossa or sella turcica; *pa*, parietal; *so*, supra-occipital; *sq*, squamosal; 3, foramen lacerum medium; 4, foramen ovale (near it in front is foramen rotundum, behind externally is foramen spinosum); 6, foramen lacerum posterius (just beneath *o* is foramen lacerum anterius); 7, meatus auditorius internus, in the petrous portion of temporal, between which and orbitosphenoid is the middle fossa, before which fossa is the anterior fossa; behind the middle fossa is the posterior or cerebellar fossa. 6 is in foramen magnum.

bones, the formation of each half of the lower jaw by several recognizable pieces, and especially by the intervention of a movable quadrate bone between the squamosal and the mandible. Some other additional bones make their appearance; and the occipital condyle is always single. A skull of similar construction to that of birds characterizes reptiles proper; but here again the cranial is small in comparison with the facial region (as in the lower mammals), sometimes excessively so; the skull is more loosely constructed, with fewer ankyloses of its several elements; and some additional bones not found in any higher vertebrates first appear. The skulls of batrachians differ widely from all the above. Some additional elements appear; some usually ossified elements may be persistently cartilaginous; and branchial as well as hyoidean arches are seen to be parts of the skull. The further modifications of the skull in fishes are great and diversified: not only is there much variation in the skulls of different fishes, but also the difference between any of their skulls and those of higher vertebrates is so great that some of the bones can be only doubtfully homologized with those of higher vertebrates, while of others no homologues can be recognized. In these ichthyopsidan vertebrates, also, the skull is sometimes permanently cartilaginous, as in selachians; in the lampreys the lower jaw disappears; in the lancelets there is no skull. In fishes, also, more or fewer branchial arches are conspicuous parts of the skull, forming usually, with the compound lower jaw, by far the bulkier section of this collection of bones; and in some of them the connection of the shoulder-girdle with the skull is such that it is not always easy to say of certain bones whether they are more properly scapular or cranial. The natural evolution of the skull is, of course, from the lower to the higher vertebrates (the reverse of that above sketched). Above lampreys and hags, after a lower jaw has been acquired, the general course of evolution of the skull is to the reduction in number of its bones or cartilages by the entire disappearance of some and the confluence of others, tending on the whole to the compactness, simplicity, and symmetry of which the human skull is the extreme case, and in which, as in the skull of any mammal or bird, evidences of its actual osseous elements are chiefly to be traced in the transitory centers of ossification of the embryo. A good illustration of this is witnessed in the condition of the bones of the tongue (hyoid arch) in mammals; for even in birds (next below mammals) the tongue has a skeleton of several distinct bones, the position of which in a series of arches next after the mandibular and next before the branchial arches proper is evident. The base of the skull is generally laid down in cartilage. The dome of the skull and the facial parts are usually of membrane-bones; and to the latter some dermal or exoskeletal bones may be added. Facial parts of all skulls are of different character from cranial parts proper, in that they belong essentially to the series of visceral (hemal, not neural) arches: (1) upper jaw; (2) under jaw; (3) tongue (hyoid), followed by more or fewer successive branchial arches. The neural arches, or cranial segments proper, are at least 3 (some count 4) in number, named *occipital, parietal,* and *frontal,* from behind forward, represented respectively by (1) the occipital bone; (2) the basisphenoid, alisphenoid, and parietal bones; (3) the presphenoid, orbitosphenoid, and frontal bones. With these are intercalated or connected the sense-capsules of the three higher senses—namely, of hearing, sight, and smell—these being the skeletons of the ear, eye, and nose, or the petrosal parts of the temporal, the sclerotic coat of the eye, and the lateral masses of the ethmoid bone. Remaining hard parts of the head, and, as such, elements of the skull, are the teeth, borne on more or fewer bones: in mammals, when present, confined to the premaxillaries, supramaxillaries, and inframaxillaries; not present in any existing birds; in various reptiles and fishes, absent, or borne upon the bones above named, and also, in that case, upon the sphenoid, vomer, palatals, pterygoids, hyoids, pharyngeals, etc. The body of facts or principles concerning skulls is craniology, of which craniometry is one department, especially applied to the measurement of human skulls for the purposes of ethnography or anthropology. For the human skull (otherwise than as here figured), see cuts under *craniofacial, craniometry, cranium, ear*[1], *nasal, orbit, palate, parietal,* and *skeleton.* For various other mammalian skulls, see cuts under *Balænidæ, Canidæ, castor, Catarrhina, Edentata, Elephantinæ, Equidæ, Felidæ, Leporidæ, Mastodontinæ, Muridæ, ox, physeter, Pteropodidæ, ruminant, skeleton.* Birds' skulls, or parts of them, are figured under *chondrocranium, desmognathous, diploë, dromæognathous, Gallinæ. skunk early attracted attention. It is mentioned in 1636 by Sagard-Théodat by several terms based on its Indian names, as *scangaresse*, *ouinesque*, etc., and in the same passage, in his "History of Canada," this author calls it in French "*enfan du diable*," a name long afterward quoted as specific. It is the *fiskatta* of Kalm's "Travels," commonly translated *polecat*, a name, however, common to various other ill-scented *Mustelidæ*. (See def. 2.) *Chinche*, *chinga*, and *moufette* (specifically *moufette d'Amérique*) are book-names which have not been Englished. The New Latin synonyms are numerous. The animal inhabits all of temperate North America, and continues abundant in the most thickly settled regions. It is about as large as a house-cat, but stouter-bodied, with shorter limbs, and very long bushy tail, habitually erected or turned over the back. The color is black or blackish, conspicuously but to a variable extent set off with pure white — generally as a frontal stripe, a large crown-spot, a pair of broad divergent bands along the sides of the back, and white hairs mixed with the black ones of the tail. The fur is valuable, and when dressed is known as *Alaska sable*; the blackest pelts bring the best price. The flesh is edible, when prepared with sufficient care. The skunk is carnivorous, like other members of the same family, with which its habits in general agree; it is very prolific, bringing forth six or eight young in burrows. The fluid which furnishes the skunk's almost sole means of defense was long supposed and is still vulgarly believed to be urine. It is the peculiar secretion of a pair of perineal glands (first dissected by Jeffries Wyman in 1844), similar to those of other *Mustelidæ*, but very highly developed, with strong muscular walls, capacious reservoir, and copious golden-yellow secretion, of most offensive suffocating odor, capable of being spirted several feet in fine spray, and of soon scenting the air for several hundred yards. The pungent effluvium is not less durable than that of musk, when the least quantity of the fluid has been spilled upon the person or clothes. It produces nausea in some persons, and has occasionally been used in minute doses as a remedy for asthma. Cases of a kind of hydrophobia from the bite of the skunk, with fatal result, have been reported, and appear to be authentic. For technical characters, see *Mephitis*.

slang[3] (slang), *n.* [Of obscure cant origin; the form suggests a connection with *sling*, in a way indicated by the use of *sling* and *fling* in 'to *sling* epithets,' 'to *fling* reproaches,' etc., and by similar uses of related Scand. forms, as Norw. *sleng*, a slinging, a device, a burden of a song; *slengja*, sling (*slengja kjeften*, abuse, lit. 'sling the jaw'); *slengjenamn*, a nickname; *slengje-ord*, an insulting word or allusion; Icel. *slyngr*, *slyngum*, cunning: see *sling*[1]. The noun, in this view, must have arisen in quasi-composition (*slang*-patter, *slang*-word, *slang*-name, etc.), or else from the verb. Evidence of early use is lacking. The word has nothing to do with *language* or *lingo*, and there is no evidence to establish a Gipsy origin.] **1.** The cant words or jargon used by thieves, peddlers, beggars, and the vagabond classes generally; cant.

Slang in the sense of the cant language of thieves appears in print certainly as early as the middle of the last century. It was included by Grose in his "Dictionary of the Vulgar Tongue," published in 1785. But it was many years before it was allowed a place in any vocabulary of our speech that confined itself to the language of good speakers and writers. Its absence from such works would not necessarily imply that it had not been in frequent use. Still, that this never had been the case we have direct evidence. Scott, in his novel of "Redgauntlet," which appeared in 1824, when using the word, felt the necessity of defining it; and his definition shows not only that it was generally unknown, but that it had not then begun to depart at all from its original sense. In the thirteenth chapter of that work, one of the characters is represented as trying to overhear a conversation, . . . but . . . "what did actually reach his ears was disguised so completely by the use of cant words and the thieves' Latin called *slang* that, even when he caught the words, he found himself as far as ever from the sense of their conversation." No one who is now accustomed either to speak slang [in def. 2], or to speak of the users of it, would think of connecting it with anything peculiar to the language of thieves. Yet it is clear from this one quotation that the complete change of meaning which the term has undergone has taken place within a good deal less than sixty years.
The Nation, Oct. 9, 1890, p. 289.

Let proper nurses be assigned, to take care of these babes of grace [young thieves]. . . . The master who teaches them should be a man well versed in the cant language commonly called the *slang* patter, in which they should by all means excel.
Jonathan Wild's Advice to his Successor (1758). (*Hotten.*)

2. In present use, colloquial words and phrases which have originated in the cant or rude speech of the vagabond or unlettered classes, or, belonging in form to standard speech, have acquired or have had given them restricted, capricious, or extravagantly metaphorical meanings, and are regarded as vulgar or inelegant. Examples of slang are *rum* for 'queer,' *gay* for 'dissolute,' *corned*, *tight*, *slued*, etc., for 'intoxicated,' *awfully* for 'exceedingly,' *jolly* for 'surprising, uncommon,' *daisy* for something or somebody that is charming or admirable, *kick the bucket* or *hop the twig* for 'die,' etc. This colloquial slang also contains many words derived from thieves' cant, such as *pal* for 'partner, companion,' *cove* for 'fellow,' and *ticker* for 'watch.' There is a slang attached to certain professions, occupations, and classes of society, such as racing *slang*, college *slang*, club *slang*, literary *slang*, political *slang*. (See *cant*[2].) Slang enters more or less into all colloquial speech and into inferior popular literature, as novels, newspapers, political addresses, and is apt to break out even in more serious writings. Slang as such is not necessarily vulgar or ungrammatical; indeed, it is generally correct in idiomatic form, and though frequently censured on this ground, it often, in fact, owes its doubtful character to other causes. *Slang* is often used adjectively: as, a *slang* expression. See the quotations below.

The smallest urchin whose tongue could tang
Shock'd the dame with a volley of *slang*.
Hood, Tale of a Trumpet.

Cant, as used in the phrases "thieves' cant," "tinkers' cant," "printers' cant," or the cant of any craft or calling, is really a language within a language, and is intended to conceal the thoughts of those who utter it from the uninitiated. *Slang*, on the other hand, is open to all the world to use, and its ranks are recruited in various ways.
N. and Q., 7th ser., VIII. 341.

Center slang, thieves' slang in which the middle vowel of a word is taken as its initial letter, and other letters or syllables are added to give the word a finish, as *lock* becomes "ockler," *pitch*, "itchper," etc. *Ribton-Turner*, Vagrants and Vagrancy, p. 478.—**Riming slang**, a kind of cant or secret slang spoken by street vagabonds in London, consisting of the substitution of words or sentences which rime with other words or sentences intended to be kept secret: as, "apples and pears" for *stairs;* "Cain and Abel" for *a table*. 3. A rock the most striking characteristic of which is its fissile structure, or capability of being easily split or cleft into thin plates of nearly uniform thickness and smooth surfaces. The rocks in which a fissile structure is particularly well developed are almost exclusively the argillaceous, and those which have been more or less metamorphosed, and this fissility appears to be the result of the rearrangement of the particles of the rock into new combinations flattened into thin scales which lie in a direction at right angles to the direction in which the rock was pressed at the time the metamorphism was taking place. The best-known variety of slate is the common roofing-slate, which is compact, homogeneous, and fissile enough to be used for covering roofs, or for manufacture into tables, chimney-pieces, writing-slates, etc. The valuable varieties of roofing-slate come almost exclusively from the older metamorphic rocks. (See *cleavage* and *foliation*.) North Wales is by far the most important slate-producing region of the world, some beds having been worked there as early as the twelfth century. The principal quarries are in southern Carnarvonshire and Merionethshire in the Lower Silurian, and in Montgomeryshire in the Upper Silurian. There are also quarries in Cornwall in the Devonian, and slates of the same geological age are obtained in France in considerable quantity, as well as in parts of Germany adjacent to the Rhine. There are various quarries in Devonshire in the Carboniferous; but in most of them the slate furnished is not of first-rate quality; and, in general, it may be said that the Carboniferous is the highest geological formation producing what can properly be denominated *slate*. The slate of the United States comes almost entirely from a very low position in the geological series, as is also the case in Europe. Pennsylvania and Vermont are the principal slate-producing States, and they together furnish more than six sevenths in value of the total production of the country.

Serfdom died out gradually in England in the latter part of the middle ages, and slavery was abolished throughout the British empire in 1833, after long agitation, the sum of twenty million pounds sterling being paid as compensation to the slave-owners. Negro slavery was introduced into the present territory of the United States in 1620, and became recognized as an institution. The Northern States gradually got rid of their slaves by emancipation or transportation in the latter part of the eighteenth and the early part of the nineteenth century. Slavery became a leading and agitating question from the time of the Missouri Compromise (1820), and the number of slave States increased to fifteen. (See *slave State*, under *slave*[2], *a.*) President Lincoln, by his Emancipation Proclamation of January 1st, 1863, declared free all slaves in that part of the Union designated as in rebellion; and the thirteenth amendment to the Constitution, 1865, abolished slavery within the United States. Slavery has been abolished by various other countries in the nineteenth century, as by Brazil in 1888.

★**sleep** (slēp), *n.* [< ME. *sleep, slepe, slep, slape, slæp*, < AS. *slǣp* = OS. *slāp* = OFries. *slēp* = D. *slaap* = MLG. LG. *slāp* = OHG. MHG. *slāf*, G. *schlaf* = Goth. *slēps*, sleep; from the verb.] 1. A state of general marked quiescence of voluntary and conscious (as well as many involuntary and unconscious) functions, alternating more or less regularly with periods of activity. In human sleep, when it is deep, the body lies quiet, with the muscles relaxed, the pulse rate lower than during the waking hours, and the respiration less frequent but deep, while the person does not react to slight sensory stimuli. Intestinal peristalsis is diminished; secretion is less actively carried on; the pupils are contracted; and the brain is said to be anemic. If the depth of sleep is measured by the noise necessary to waken the sleeper, it reaches its maximum within the first hour and then diminishes, at first rapidly, then more slowly.

> Half in a dreme, not fully weel a-wakid,
> The golden *sleep* me wrapt vndir his wieng.
> *Political Poems*, etc. (ed. Furnivall), p. 52.
>
> Else could they not catch tender *sleep;* which still
> Is shy and fearful, and flies every voice.
> *J. Beaumont*, Psyche, iv. 41.

Sleep is a normal condition of the body, occurring periodically, in which there is a greater or less degree of unconsciousness due to inactivity of the nervous system and more especially of the brain and spinal cord. It may be regarded as the condition of rest of the nervous system during which there is a renewal of the energy that has been expended in the hours of wakefulness.
Encyc. Brit., XXII. 154.

2. A period of sleep: as, a short *sleep.*

> It seems his *sleeps* were hindered by thy railing.
> *Shak.*, C. of E., v. 1. 71.
>
> On being suddenly awakened from a *sleep*, however profound, we always catch ourselves in the middle of a dream.
> *W. James*, Prin. of Psychol., I. 201.

3. Repose; rest; quiet; dormancy; hence, the rest of the grave; death.

> Here are no storms,
> No noise, but silence and eternal *sleep*.
> *Shak.*, Tit. And., i. 1. 155.
>
> A calm, unbroken *sleep*
> Is on the blue waves of the deep.
> *Prentice*, To an Absent Wife.

4. Specifically, in *zoöl.*, the protracted and profound dormancy or torpidity into which various animals fall periodically at certain seasons of the year. Two kinds of this sleep are distinguished as *summer* and *winter sleep*, technically known as *estivation* and *hibernation* (see these words).

5. In *bot.*, nyctitropism, or the sleep-movement of plants, a condition brought about in the foliar or floral organs of certain plants, in which they assume at nightfall, or just before, positions unlike those which they have maintained during the day. These movements in the case of leaves are usually drooping movements, and are therefore suggestive of rest, but the direction of movement is different in different cases. Thus, among the *Oxalidaceæ* the sleep-movement consists in the downward sinking of the leaflets, which become at the same time folded on themselves. Among leguminous plants, the leaflets, in some cases, simply sink vertically downward (*Phaseoleæ*); in others, they sink down while the main petiole rises (terminal leaflet of *Meibomia*); in others, they sink downward and twist on their axes so that their upper surfaces are in contact beneath the main petiole (*Cassia*); in others, again, they rise and bend backward toward the insertion of the petiole (*Coronilla*); in others, they rise, and the main petiole rises also, whereas in *Mimosa pudica* the leaflets rise and bend forward, while the main petiole falls. In *Marsilea* the leaflets rise up, the two upper ones being embraced by the two lower. (*S. H. Vines.*) The mechanism of these movements is explained by Pfeffer and others as due to an increased growth on one side of the median line of the petiole or midrib, followed, after a certain interval of time, by a corresponding growth on the opposite side. It is also accomplished by simple turgescence of opposite sides. The utility of the sleep-movements is believed to consist in protection from too great radiation. The cause or causes of these movements (and of analogous movements which have been called *diurnal* sleep: see the second quotation) are only imperfectly known, but they are undoubtedly largely due to sensitiveness to variations in the intensity of light. See *nyctitropism.*

> Those movements which are brought about by changes in the amount of light constitute what are known as the "*sleep*" and "waking" of plants. *Bessey*, Botany, p. 198.
>
> There is another class of movements, dependent on the action of light. . . . We refer to the movements of leaves and cotyledons which when moderately illuminated are diaheliotropic, but which change their positions and present their edges to the light when the sun shines brightly on them. These movements have sometimes been called diurnal *sleep.* *Darwin*, Movement in Plants, p. 445.

(*b*) In *milit. engin.*, one of the small joists of wood which form the foundation for a battery platform. (*c*) A piece of wood, metal, or other material upon which the rails or the rail-chairs of a railway rest, and to which they are fastened. Wood of durable varieties is far more extensively used for this purpose than any other material; but stone, toughened glass, and iron have also been used, the last to a considerable extent. In some instances the sleepers are laid longitudinally with the rails, and bound together by cross-ties. This system is in use on some important European railways, and generally on elevated railways and street railways, both in the United States and elsewhere; but the most common method is to lay the sleepers at right angles to the rails, and about 2 feet from center to center, except when they support points and angle-bars, when they are placed 1 foot 6 inches from center to center. They are thus made to act both as sleepers and as cross-ties. Such sleepers are in the United States also called *railway-ties* or simply *ties.* See cut under *rail-chair.*

Well-developed slickensides are most frequently seen in connection with mineral veins, but the sides of joints in non-metalliferous rocks occasionally exhibit this kind of striation. Slickensided surfaces are frequently coated with a thin film of pyrites, galena, hematite, or some other mineral, which may be polished so as to reflect the light like a mirror (whence the French name *miroirs*).

Nearly akin to this jointed character are the *slickensides*, or polished and striated surfaces, which, sometimes of iron pyrites, but more usually of copper pyrites, often cover the faces of the walls of lodes. *Henwood*, Metalliferous Deposits of Cornwall and Devon, [p. 181.

4. A South American tardigrade edentate mammal of the family *Bradypodidæ:* so called from their slow and apparently awkward or clumsy movements. The slowness of their motions on the ground is the necessary consequence of their disproportioned structure, and particularly of the fact that the feet exhibit a conformation resembling that of clubfoot in man—a disposition of the carpal and tarsal joints highly useful in climbing. Sloths live on trees, and never remove from one until they have stripped it of every leaf. They are helpless when on the ground, and seem at home only on trees, suspended beneath the branches, along which they are sometimes observed to travel from tree to tree with considerable celerity. The female produces a single young one at a birth, which she carries about with her until it is able to climb. Sloths are confined to the wooded regions of tropical America, extending northward into Mexico. At least 12 species are described, but the true number is fewer. All have three toes on the hind feet, but some have only two on the fore feet, whence the obvious distinction of *three-toed* and *two-toed* sloths (a distinction even more strongly marked in the anatomy of these animals) warranted a division of the family into bradypods (*Bradypodinæ*) and cholopodines (*Cholopodinæ*). Most sloths belong to the former group, and these have the general name *ai*. The best-known of these is the collared three-toed sloth, *Bradypus tridactylus* or *torquatus*, with a sort of mane. The unau or two-toed sloth, *Cholopus didactylus*, inhabits Brazil; it is entirely covered with long coarse woolly hair. (See cut under *Cholopus*.) A second and quite distinct species of this genus, *C. hoffmanni*, inhabits Central America. (See *Tardigrada*, 1.) The name is apparently a translation of the Portuguese word *preguiça* (Latin *pigritia*), slowness, slothfulness. See the quotation.

Here [in Brazil] is a Beast so slow in motion that in fifteen days he cannot go further than a man can throw a stone; whence the Portugals call it Pigritia.

smell (smel), *n.* [< ME. *smel, smil, smul, smeal, smeol* (not found in AS.): see the verb.] 1. The faculty of perceiving by the nose; sense-perception through the olfactory nerves; the olfactory faculty or function; the physiological process or function whereby certain odoriferous qualities of bodies, as scent or effluvium, are perceived and recognized through sensation; olfaction; scent: often with the definite article, as one of the special senses: as, *the smell* in dogs is keen. The essential organ of smell is located in a special part or lobe of the brain, the rhinencephalon, or olfactory lobe, whence are given off more or fewer olfactory nerves, which pass out of the cranial cavity into the nasal organ, or nose, in the mucous or Schneiderian membrane of the interior of which they ramify, so that air laden with odoriferous particles can affect the nerves when it is drawn into or through the nasal passages. In man the sense of smell is very feeble and imperfect in comparison with that of many animals, especially of the carnivores, which pursue their prey by scent, and ruminants, which escape their enemies by the same means. Smell in the lower animals seems to be the guiding sense in determining their choice of food.

Memory, imagination, old sentiments and associations, are more readily reached through the sense of *smell* than by almost any other channel. *O. W. Holmes,* Autocrat, iv.

Smell is a sensation excited by the contact with the olfactory region of certain substances, usually in a gaseous condition and necessarily in a state of fine subdivision.

2. That quality of anything which is or may be smelled; an odoriferous effluvium; an odor or scent, whether agreeable or offensive; a fragrance, perfume, or stench; aroma: as, the *smell* of thyme; the *smell* of bilge-water.

Suettere *smul* ne myȝte be then the smoke smulde.

3. A faint impression; a subtle suggestion; a hint; a trace: as, the poem has a *smell* of the woods.—4. An act of smelling: as, he took a *smell* at the bottle.—**Syn.** *Smell, Scent, Odor, Savor, Perfume, Fragrance, Aroma, Stench, Stink.* *Smell* and *scent* express the physical sense, the exercise of the sense, and the thing which appeals to the sense. The others have only the last of these three meanings. Of the nine words the first four may express that which is pleasant or unpleasant, the next three only that which is pleasant, the last two only that which is very unpleasant. *Smell* is the general word; the others are species under it. *Scent* is the smell that proceeds naturally from something that has life: as, the *scent* of game; the *scent* of the tea-rose. *Odor* is little more than a Latin substitute for *smell:* as, the *odor* of musk, of decaying vegetation; it may be a dainty word, as *smell* cannot be. *Savor* is a distinctive smell, suggesting taste or flavor, proceeding especially from some article of food: as, the *savor* of garlic. *Perfume* is generally a strong or rich but agreeable smell. *Fragrance* is best used to express fresh, delicate, and delicious odors, especially such as emanate from living things: as, the *fragrance* of the violet, of new-mown hay, of the breath of an infant. *Aroma* should be restricted to a somewhat spicy smell: as, the *aroma* of roasted coffee, or of the musk-rose. *Stench* and *stink* are historically the same word, in different degrees of strength, representing a strong, penetrating, and disgusting odor; *stink* is not for polite use.

Metallurgical operations carried on in the moist way, as the amalgamation of gold and silver ores in pans, treatment by lixiviation, etc., are not generally designated by the term *smelting.* Establishments where this is done are more commonly called mills or reduction-works, and those in which iron is smelted are usually designated as blast-furnaces or iron-furnaces. The vari-

ous smelting operations differ greatly from each other, according to the nature of the combinations operated on. Simple ores, like galena, require only a very simple series of operations, which are essentially continuous in one and the same furnace; more complicated combinations, like the mixtures of various cupriferous ores smelted at Swansea by the English method, require several successive operations, entirely disconnected from each other, and performed in different furnaces. In the most general way, the essential order of succession of the various processes by which the sulphureted ores (and most ores are sulphurets) are treated is as follows: (1) calcination or roasting, to oxidize and get rid (as far as possible) of the sulphur; (2) reduction of the metal contained in the oxidized combinations obtained; (3) refining, or getting rid of the last traces of deleterious metals associated in the ores with the useful metal, to obtain which is the essential object of the operation.

II. *intrans.* To fuse; melt; dissolve.

ulated veins between the three or more prominent nerves. The petioles are persistent at the base, and are often furnished with two tendrils, by which some species climb to great heights, and others mat into densely tangled thickets. The rootstocks of many species are large and tuberiferous; those of *S. Pseudo-China* are used in the southern United States to fatten hogs, and as the source of a domestic beer; those of *S. China* yield a dye. The stems of some pliant species, as *S. Pseudo-China*, are used in basket-making, and the young shoots of a Persian species are there used as asparagus. *S. Pseudo-China* and *S. To apply smoke to; blacken with smoke; hang in smoke; medicate or dry by smoke; fumigate: as, to *smoke* infected clothing; to subject to the action of smoke, as meat; cure by means of smoke; smoke-dry; also, to incense. Smoking meat consists in exposing meat previously salted, or rubbed over with salt, to wood-smoke in an apartment so distant from the fire as not to be unduly heated by it, the smoke being admitted by flues at the bottom of the side walls. Here the meat absorbs the empyreumatic acid of the smoke, and is dried at the same time. The kind of wood used affects the quality and taste of the meat, smoke from beech and oak being preferable to that from fir and larch. Smoke from the twigs and berries of juniper, or from rosemary, peppermint, etc., imparts somewhat of the aromatic flavor of these plants. A slow smoking with a slender fire is better than a quick and hot one, as it allows the empyreumatic principles time to penetrate into the interior without over-drying the outside.

It is the most destructive disease of wheat known, not infrequently causing the loss of half of the crop or more. It occurs to some extent throughout all the wheat-growing regions, but is especially common in Indiana, Iowa, and adjacent States, as well as in California and Europe. The disease does not spread from plant to plant or from field to field, but the infection takes place at the time the seed sprouts. No remedy can be applied after the grain is sown, but the disease can be prevented by sowing clean seed in clean soil and covering well. Smutty seed can be purified by wetting thoroughly with a hot-water solution of blue vitriol, using one pound or more to a gallon of water. Black smut may be similarly treated. *U. Zeæ* is the smut of Indian corn; *U. panici-glauca*, of *Chætochloa glauca;* *Cintractia caricis*, of many species of *Carex;* etc. See *Ustilago*, *Tilletia*, *maize-smut*, *bunt*[4], *bunt-ear*.

The line is then dropped into some quiet place where fish are plentiful, . . . and, as soon as the plummet has touched the bottom, is twitched violently up. It is almost a certainty that on some one or other of the hooks, and possibly on more than one, will be a fish foul-hooked.

A bird of the genus *Scolopax* in a former broad sense. (*a*) Some or any bird belonging to the family *Scolopacidæ*, having the bill straight, much longer than the head, dilated and sensitive at the end, and with a median lengthwise groove on the upper mandible near the end, the toes cleft to the base, the primaries not emarginate, and the tail-feathers barred; especially, a member of the genus *Gallinago* (*Scolopax* being restricted to certain woodcock). In Great Britain three species of *Gallinago* are called *snipe*. (1) The common snipe, or whole-snipe, is *Gallinago cœlestis* or *G. media*, formerly *Scolopax gallinago*. (2) The great, double, or solitary snipe, or woodcock-snipe, is *G. major*. (3) The small snipe, half-snipe, or jack-snipe is *G. gallinula*. They differ little except in size. In the United States the common snipe, also called *jack-snipe* and *Wilson's snipe*, is *G. wilsoni* or *G. delicata*, about as large as *G. media*, which it very closely resembles, so that it is sometimes known as the "English" snipe, to distinguish it from various snipe-like birds peculiar to America, and also *bog-snipe*, *gutter-snipe*, *meadow-snipe*, *alewife-bird*, *shad-bird*, and *shad-spirit*. It is from 10½ to 11½ inches long and from 17½ to 19½ in extent of wings; the bill is about 2½ inches long. The upper parts are blackish, varied with bay and tawny; the scapulars are edged with tawny or pale buff, forming a pair of firm stripes along the sides of the back when the wings are closed; the lining of the wings and axillary feathers is barred regularly with black and white; the tail-feathers, normally sixteen in number, are barred with black, white, and chestnut; the fore neck and breast are light-brown speckled with dark-brown; and the belly is white. (See cut under *Gallinago*.) Snipes like these, and of the same genus, are found in most countries, and are called by the same name, with or without a qualifying term. (*b*) Some other scolopacine or snipe-like bird. There are very many such birds, chiefly distinguished from sandpipers (see *sandpiper*) by the length, from tattlers or gambets by the sensitiveness, and from curlews, godwits, etc., by the straightness of the bill. (1) In the United States the gray-backed or red-breasted snipes are birds of the genus *Macrorhamphus*, of which there are 2 species or varieties, the lesser and greater longbeak, *M. griseus* and *M. scolopaceus*. See *dowitcher*. (2) The grass-snipe is the pectoral sandpiper, *Actodromas maculata*. See cut under *sandpiper*. Also called *jack-snipe*. (3) The robin-snipe is the knot, *Tringa canutus*, also a sandpiper. (4) The stone-snipe is *Totanus melanoleucus*, a tattler. See cut under *yellowlegs*. (5) In Great Britain the sea-snipe is the dunlin, *Tringa* or *Pelidna alpina*, a sandpiper. (6) In Great Britain the summer snipe is the common sandpiper, *Actitis hypoleucus*. (7) Painted snipe are the curious birds of the genus *Rhynchæa* or *Rostratula*. See these words. (*c*) A common misnomer, in various localities, of the American woodcock, *Philohela minor:* also called *common snipe*, *big snipe*, *mud-snipe*, *red-breasted snipe*, *big headed snipe*, *blind snipe*, *whistling snipe*, *wood-snipe*. they present uncounted varieties of very beautiful figures. The whiteness of snow is due primarily to the large number of reflecting surfaces arising from the minuteness of the crystals. When sufficient pressure is applied, the slightly adhering crystals are brought into molecular contact, and the snow, by regelation, becomes converted into solid ice. This change takes place when snow is gradually transformed into the ice of a glacier. Precipitation takes the form of snow when the temperature of the vapor in the atmosphere is near or below the freezing-point, and the flakes are larger the moister the air and the higher its temperature. The annual depth of snowfall and the number of days on which the ground is covered with snow are important elements of climate. In a ship's log-book abbreviated *s.*

snow-line (snō′līn), *n.* The limit of continual snow, or the line above which a mountain is continually covered with snow. The snow-line is due primarily to the decrease of the temperature of the atmosphere with increase of altitude. In general, the height of the snow-line diminishes as we proceed from the equator toward the poles; but there are many exceptions, since the position of the snow-line depends not only upon the mean temperature, but upon the extreme heat of summer, the total annual snowfall, the prevalent winds, the topography, etc. For these reasons, the snow-line is not only at different heights in the same latitude, but its position is subject to oscillation from year to year in the same locality. Long secular oscillations in the height of the snow-line are evidence of corresponding oscillations of climate. In the Alps the snow-line is at an altitude of 8,000 to 9,000 feet; in the Andes, at the equator, it is nearly 16,000 feet.

Between the glacier below the ice-fall and the plateau above it there must exist a line where the quantity of snow which falls is exactly equal to the quantity annually melted. This is the *snow-line*.

A modification of the latter is adapted to street-railroads. The snow-plow for ordinary country roads usually consists of a frame of boards braced together so as to form an acute angle in front, and spread out behind to any required distance. In recent forms the principle of centrifugal force has been utilized for removal of the snow. Snow-plows are often of great size, sometimes weighing fifty tons, and can be forced through very deep drifts.

It has a light rim of tough wood, on which is woven from side to side a web of rawhide. The Norwegian is merely a thin board, about 8 feet long and 3 inches wide, slightly curved upward in front; it is especially adapted to mountains, in descending which by its use great speed is attained. When the slender shaft is thrown, it glides rapidly over the surface, with upraised head and a quivering motion, that gives it a strange resemblance to a living creature. . . . Fats and fixed oils consist of fatty acids combined with glycerin. On treating them with a strong base, like potash or soda, glycerin is set free, and the fatty acid combines with the strong base and forms a soap. Soap is of two kinds—*soluble* soap, in which the base is potash, soda, or ammonia, and *insoluble* soap, whose base is an earth or a metallic oxid. Only the soluble soaps dissolve readily in water and have detergent qualities. Insoluble soaps are used only in pharmacy for liniments or plasters. Of the fats, stearates make the hardest, oleates the softest soaps; and of the bases, soda makes the hardest and least soluble, and potash the softest and most soluble. Perfumes are occasionally added, or various coloring matters are stirred in while the soap is semi-fluid. White soaps are generally made of olive-oil and soda. Common household soaps are made chiefly of soda and tallow. Yellow soap is composed of tallow, rosin, and soda, to which some palm-oil is occasionally added. (See *rosin-soap.*) Mottled soap is made by simply adding mineral and other colors during the manufacture of ordinary hard soap. Marine soap, known as *salt-water soap,* which has the property of dissolving as well in salt water as in fresh, is made of palm- or cocoanut-oil and soda. Soft soaps are made with potash, instead of soda, and whale-, seal-, or olive-oil, or the oils of linseed, hemp-seed, rape-seed, etc., with the addition of a little tallow. Excellent soaps are made from palm-oil and soda. A solution of soap in alcohol, with camphor and a little essential oil added to scent it, forms a soft ointment called *opodeldoc,* now superseded by soap-liniment, a similar preparation, which is liquid. Medicinal soap, when pure, is prepared from caustic soda and either olive- or almond-oil. It is chiefly employed to form pills of a gently aperient antacid action.

Saponaria,* a small tree of South America, the West Indies, and Florida, is much used in the West Indies for cleansing linen, etc., and is said to be extremely efficacious, though with frequent use deleterious to the fabric. Its roots also contain saponin. Its hard black seeds are made up into rosaries and necklaces, and sometimes have been used as buttons. In the East Indies the fruit of *S. trifoliatus* appears to have been used as a detergent from remote times. The pulp is regarded also as astringent, anthelmintic, and tonic, and the seeds yield a medicinal oil. The wood is made into combs and other small articles. This species is sometimes called *Indian filbert,* translating the Mohammedan name. *S. (Dittelasma) Rarak,* of Cochin-China, etc., has also a detergent property. The wood of *S. Drummondi* and *marginatus,* of the southern United States, etc., is hard and strong, easily split into strips, and in the southwest much used for making cotton-baskets and the frames of pack-saddles. Its berries are reddish-brown, of the size of a cherry, with a soapy pulp. Also called *wild china-tree* (which see, under *china-tree*). The fruit of some species yields an edible pulp, though the seed is poisonous. Another name, especially of *S. trifoliatus,* is *soapnut.*

To mount on wings, or as on wings, through the air; fly aloft, as a bird or other winged creature; specifically, to rise and remain on the wing without visible movements of the pinions. The specific mode of flight is specially distinguished from any one in which the wings are flapped to beat the air; but the term *soaring* is also loosely applied to any light, easy flight to a great height with little advance in any other direction, whatever be the action of the wings, as of a skylark rising nearly vertically from the ground. In the case of heavy-bodied, short-winged birds which fly up thus, the action is often specified as *rocketing* or *towering* (see these verbs). A kind of swift wayward soaring, as of the swallow, is often called *skimming*. Soaring specifically so called, or sailing on the air, is best shown in the flight of long-winged birds, whether their wings be either narrow and sharp, or ample and blunt, as the albatross, frigate, and some other sea-birds, storks, cranes, and some other large waders, turkey-buzzards and other vultures, eagles, kites, and some other large birds of prey. It is capable of being indefinitely protracted, either on a horizontal plane, or at a considerable inclination upward, at least in some cases; but most birds which soar to a higher level without beating the wings take a spiral course, mounting as much as they can on that part of each lap which is against the wind, and this action is usually specified as *gyrating* or *circling*.

So have I seen a lark rising from his bed of grass, and *soaring* upwards, singing as he rises, and hopes to get to heaven, and climb above the clouds. *Jer. Taylor*, Sermon, The Return of Prayers, ii.

For the present its members content themselves with the promotion of measures for the amelioration of the condition of the working classes, such as shortening the hours of labor, forbidding the employment of children in factories, and higher education for all. Social Democrats are now found in many of the countries of Europe, as well as in the United States. socialism (sō′shal-izm), *n.* [= F. *socialisme* = Sp. Pg. *socialismo* = G. *socialismus*; as *social* + *-ism*.] Any theory or system of social organization which would abolish, entirely or in great part, the individual effort and competition on which modern society rests, and substitute for it coöperative action, would introduce a more perfect and equal distribution of the products of labor, and would make land and capital, as the instruments and means of production, the joint possession of the members of the community. The name is used to include a great variety of social theories and reforms which have more or less of this character.

What is characteristic of *socialism* is the joint ownership by all the members of the community of the instruments and means of production; which carries with it the consequence that the division of the produce among the body of owners must be a public act performed according to rules laid down by the community. *Socialism* by no means excludes private ownership of articles of consumption. *J. S. Mill*, *Socialism*.

Socialism, . . . while it may admit the state's right of property over against another state, does away with all ownership, on the part of members of the state, of things that do not perish in the using, or of their own labor in creating material products.
Woolsey, Communism and *Socialism*, p. 7.

Christian socialism, a doctrine of somewhat socialistic tendency which sprang up in England about 1850, and flourished under the leadership of Charles Kingsley, Frederick D. Maurice, Thomas Hughes, and others. The main contentions of its advocates were (1) that Christianity should be directly applied to the ordinary business of life, and that in view of this the present system of competition should give place to coöperative associations both productive and distributive, where all might work together as brothers; (2) that any outer change of the laborer's life, as aimed at in most socialistic schemes, would not suffice to settle the labor question, but that there must be an inner change brought about by education and elevation of character, especially through Christianity; and (3) that the aid of the state should not be invoked further than to remove all hostile legislation. A similar scheme appeared somewhat earlier in France. The doctrines of Christian socialism, or similar doctrines under the same name, have been frequently advocated in the United States.—**Professorial socialism.** Same as *socialism of the chair*.—**Socialism of the chair,** a name (first used in ridicule in 1872 by Oppenheim, one of the leaders of the National Liberals) for the doctrines of a school of political economy in Germany which repudiated the principle of laisser-faire, adopted in the study of political economy the historical method (which see, under *historical*), and strove to secure the aid of the state in bringing about a better distribution of the products of labor and capital, especially to bring to the laborer a larger share of this product, and to elevate his condition by means of factory acts, savings-banks, sanitary measures, shortening of the hours of labor, etc.

Socinianism (sō-sin'i-an-izm), *n.* [< *Socinian* + *-ism*.] The doctrines of the Italian theologians Lælius Socinus (1525–62) and Faustus Socinus (1539–1604) and their followers. The term is in theological usage a general one, and includes a considerable variety of opinion. The Socinians believe that Christ was a man, miraculously conceived and divinely endowed, and thus entitled to honor and reverence, but not to divine worship; that the object of his death was to perfect and complete his example and to prepare the way for his resurrection, the necessary historical basis of Christianity; that baptism is a declarative rite merely, and the Lord's Supper merely commemorative; that divine grace is general and exerted through the means of grace, not special and personally efficacious; that the Holy Spirit is not a distinct person, but the divine energy; that the authority of Scripture is subordinate to that of the reason; that the soul is pure by nature, though contaminated by evil example and teaching from a very early age; and that salvation consists in accepting Christ's teaching and following his example. The Socinians thus occupy theologically a midway position between the Arians, who maintain the divinity of Jesus Christ, but deny that he is coequal with the Father, and the Humanitarians, who deny his supernatural character altogether.

Socratic (sō-krat'ik), *a.* and *n.* [= F. *Socratique* = Sp. *Socrático* = Pg. It. *Socratico*, < L. *Socraticus*, < Gr. Σωκρατικός, of or pertaining to Socrates, < Σωκράτης, Socrates.] **I.** *a.* Of or pertaining to the methods, style, doctrine, character, person, or followers of the illustrious Athenian philosopher Socrates (about 470–399 B. C.). His father, Sophroniscus, was a sculptor, and he was brought up to the same profession. His mother, Phænarete, was a midwife. Socrates was unjustly accused before the council of the prytanes of being a corrupter of youth and of not believing in the gods of the city, was condemned, and died by drinking hemlock. His philosophy is known to us by the account of Xenophon, written to show the practical upshot of his teachings and the injustice of his sentence, and by the Dialogues of Plato, in most of which Socrates is introduced only to give an artistic setting to Plato's own discussions. Some things can also be inferred from fragments of Æschines, and from the doctrines of other companions of Socrates. He wrote nothing, but went about Athens frequenting some of the best houses, and followed by a train of wealthy young men, frequently cross-questioning those teachers whose influence he distrusted. He himself did not profess to be capable of teaching anything, except consciousness of ignorance; and he bargained for no pay, though he no doubt took moderate presents. He called his method of discussion (the *Socratic method*) *obstetrics* (see *maieutic*), because it was an art of inducing his interlocutors to develop their own ideas under a catechetical system. He put the pretentious to shame by the practice of *Socratic irony*, which consisted in sincerely acknowledging his own defective knowledge and professing his earnest desire to learn, while courteously admitting the pretensions of the person interrogated, and in persisting in this attitude until examination made it appear bitter sarcasm. He was opposed to the rhetorical teaching of the sophists, and had neither interest nor confidence in the physical speculations of his time. The center of his philosophy, as of all those which sprang directly or indirectly from his—that is to say, of all European philosophy down to the rise of modern science—was morality. He held that virtue was a species of knowledge; really to know the right and not to do it was impossible, hence wrong-doers ought not to be punished; virtue was knowledge of the truly useful. He was far, however, from regarding pleasure as the ultimate good, declaring that if anything was good in itself, he neither knew it nor wished to know it. The great problems he held to consist in forming general conceptions of the nature of truth, happiness, virtue and the virtues, friendships, the soul, a ruler, a suit of armor—in short, of all objects of interest. These conceptions were embodied in definitions, and these definitions were framed by means of analytic reflection upon special instances concerning which all the world were agreed. He would not allow that anything was known for certain concerning which competent minds opined differently. This process of generalization, the *Socratic induction*, together with the doctrine of the necessity of definitions, were his two contributions to logic. The disciples of Socrates were Plato, Euclides, Phædo, Antisthenes, Aristippus, Xenophon, Æschines, Simonias, Cebes, and about twenty more. Properly speaking, there was no Socratic school; but the Academy and the Megarian, Elean, Eretrian, Cynic, and Cyrenaic schools are called *Socratic*, as having been founded by immediate disciples of Socrates.—**Socratic school.** See *school*[1].

Dan. *soda* (NL. *soda*), < It. *soda*, soda, OIt. *soda* (= OF. *soulde*), saltwort, glasswort, fem. of *sodo*, contr. of *solido*, solid, hard: see *solid*.] **1.** Sesquicarbonate or normal carbonate of sodium (Na_2CO_3); soda-ash: the latter being the common name of the commercial article, one of the most largely used and important of all the products of chemical manufacture. Various hydrated carbonates of sodium occur in nature—the decahydrate or natron; the monohydrate, known as *thermonatrite*; and trona, a compound of the normal carbonate and the bicarbonate with two equivalents of water. These natural carbonates occur in solution in the water of various alkaline lakes, or as deposits at the bottoms of such as have become dried up, but usually mixed with more or less common salt, sodium sulphate, and other saline combinations. It was from these deposits, and from the incineration of various plants growing by the sea-shore (*Salsola*, *Salicornia*, *Chenopodium*, *Statice*, *Reaumuria*, *Nitraria*, *Tetragonia*, *Mesembryanthemum*), that soda was formerly obtained. These sources have become of little importance since artificial soda began to be made from common salt, a process invented by Leblanc, and put in operation near Paris toward the end of the eighteenth century. By this process common salt is decomposed by sulphuric acid, and the resulting sodium sulphate is mixed with limestone and coal, and heated in a reverberatory furnace, the product (technically known as *black ash*) consisting essentially of soluble sodium carbonate and insoluble calcium sulphid, which are easily separated from each other by lixiviation. By the Leblanc process the soda used in the arts was almost exclusively produced until about forty years ago, when the so-called ammonia or Solvay process began to become of importance. This process had been patented in England as early as 1838, and tried there and near Paris, but without success. The difficulties were first overcome by E. Solvay, who in 1861 established a manufactory of soda by this process (since known by his name) near Brussels. By the ammonia or Solvay process a concentrated solution of common salt is saturated with ammonia, and then decomposed by carbonic acid. By this means sodium chlorid is converted into sodium bicarbonate, and the ammonia afterward recovered by the aid of lime or magnesia. This process has within the past few years become of great importance, and at the present time the greater part of the soda of the world is made by it. Whether it will eventually entirely supplant the Leblanc process cannot yet be stated. The chief advantage which it presents is that the amount of coal consumed by it is much smaller than that required by the older process, so that countries where fuel is not very cheap and abundant can now make their own soda, being no longer dependent on England, as they were in large degree before the Solvay process became successful. For the properties of pure soda, see *sodium carbonate*, under *sodium*. Also called *mineral alkali*.

★**sodium** (sō′di-um), *n.* [= F. G. *sodium* = Sp. Pg. It. *sodio,* < NL. *sodium,* < *soda* + *-ium.*] Chemical symbol, Na (natrium); atomic weight, 23.00. The metallic base of the alkali soda. See *soda* and *metal.* It was first isolated by Davy, in 1807, by electrolysis of caustic soda, and is obtained on a large scale by the same process. Sodium is a silver-white metal with a high luster, but it oxidizes rapidly on exposure to moist air. Heated in the air, it burns rapidly with a bright-yellow flame, very characteristic of the metal; thrown into cold water, it oxidizes, but does not become hot enough to set the evolved hydrogen on fire, as potassium does; with hot water, ignition of the hydrogen takes place. Its specific gravity at 56° is 0.9755; at the ordinary temperature it has the consistency of wax; at 204° it melts, and forms a liquid resembling mercury in appearance. Next to silver, copper, and gold, it is, of the metals, the best conductor of heat and electricity; next to cæsium, rubidium, and potassium, it is the most electropositive of the metals. It is extensively used in the laboratory as a powerful reducing agent; it is closely analogous to potassium in its chemical relations. Two of its compounds are very widely diffused in nature, and of the highest importance from various points of view; these are common salt and sodium carbonate, or soda.—**Sodium bicarbonate,** a compound having the formula $NaHCO_3$. It is a white crystalline powder, with a weaker alkaline taste than the other carbonate described below, and less soluble in water. Also called *soda saleratus.*—**Sodium borate.** See *borax.*—**Sodium carbonate,** a compound having the formula Na_2CO_3, either anhydrous or containing water of crystallization. (The method of manufacture is described under *soda.*) Anhydrous sodium carbonate, or chemically pure soda, is a white powder having an alkaline taste and reaction, readily soluble in water with evolution of heat. It fuses at a dull-red heat to a clear liquid. It is used in enormous quantities in the arts for a great variety of purposes. When crystallized from aqueous solution it forms transparent crystals, called *washing-crystals,* which contain ten equivalents of water. These effloresce on exposure to air.—**Sodium chlorid,** common salt, NaCl. See *salt*[1], 1.—**Sodium line,** the bright-yellow line (strictly a double line) which incandescent sodium vapor gives when viewed by the spectroscope: it corresponds to the dark absorption-line D (D_1 and D_2) of the solar spectrum.—**Sodium nitrate.** See *nitrate of soda,* under *nitrate.*

Solanaceæ (sol-ā-nā'sē-ē), *n. pl.* [NL. (Haller, 1742), < *Solanum* + *-aceæ*.] A family of dicotyledonous sympetalous plants, of the order *Polemoniales*, characterized by regular flowers commonly with a plicate border, carpels with many ovules, and a straight, spiral, or coiled embryo in fleshy albumen. The sepals, petals, and stamens are each usually five, the ovary usually entire and two-celled, with an undivided style. In Engler's system it is placed in the subseries (suborder) *Solanineæ* between the small family *Nolanaceæ* and the *Scrophulariaceæ*. The family embraces about 1,600 species classed in 83 genera and 5 tribes, the *Nicandreæ*, *Solaneæ*, *Datureæ*, *Cestreæ*, and *Salpiglossideæ*. They are erect or climbing herbs or shrubs, or sometimes trees, and either smooth or downy, but rarely with bristles. They bear alternate and entire toothed or dissected leaves, often in scattered unequal pairs, but never truly opposite. The typical inflorescence is a bractless cyme, either terminal, opposite the leaves, or lateral, but not truly axillary, and sometimes converted into umbels or sessile clusters or reduced to a single flower. They are usually rank-scented and possess strongly narcotic properties, either throughout or in special organs, in *Mandragora* in the root, in most others strongly developed in the leaves, as in belladonna, tobacco, henbane, stramonium, and nightshade. In some, as the henbane, this principle is actively developed for a limited time only; in others, parts from which it is absent furnish a valued food, as the potato, tomato, and egg-plant, or a condiment, as Cayenne pepper. The family furnishes also several tonics and numerous diuretic remedies, as species of *Physalis*, *Nicandra*, *Cestrum*, and *Solanum*. Plants of this family are widely dispersed through warm climates of both hemispheres, extending beyond the tropics in North and South America, especially in the west, but less frequent in Europe and Asia. They are absent in alpine and arctic regions and in Australia. About 20 genera occur in North America exclusive of Mexico, notably the genera *Lycium*, *Solanum*, and *Physalis*. For other important genera, see *Lycopersicon*, *Capsicum*, *Datura*, *Nicotiana*[1], *Petunia*, and *Solandra*.

soland (sō'land), *n.* See *solan*.

solander[1] (sō-lan'dėr), *n.* Same as *sellanders*.

solander[2] (sō-lan'dėr), *n.* [< *Solander* (see quot. and *Solandra*).] A form of box designed to contain prints or drawings. See the quotation.

A *Solander* case is the invention of Dr. Solander, of memory dear to readers of "Cook's Voyages," who used one to contain and preserve specimens for natural history, drawings, and matters of the kind. It is really a box, generally shaped like a book, one side of which, turning on hinges, serves for a lid, while the front, or fore edge of the case, is furnished with hinges to be let down, so that the fronts as well as the tops of the contents can be got at.
N. and Q., 7th ser., VII. 135.

Solandra (sō-lan'drä), *n.* [NL. (Swartz, 1787), named after Daniel *Solander* (born 1736, died about 1781), a Swedish botanist and traveler.] An untenable name for *Ceratina*, a genus of solanaceous plants. It is characterized by solitary flowers with a long calyx-tube, an obliquely funnel-shaped corolla with broad imbricated lobes and induplicate sinuses, five stamens, and a two-celled ovary imperfectly four-celled by false partitions, forming in fruit a pulpy berry half-protruded from the torn membranous calyx. The 6 species are all American and tropical. They are lofty climbing coarse shrubby plants, with entire smooth fleshy and coriaceous shining leaves, clustered near the ends of the branches, and very large terminal white, yellowish, or greenish flowers on fleshy pedicels. *Ceratina grandiflora* (*Solandra grandiflora*) and other species are sometimes cultivated from the West Indies under the name *trumpet-flower*, forming handsome greenhouse evergreens, usually grown as climbers, or, in *Ceratina longiflora* (*Solandra longiflora*), as small shrubs.

Solaneæ (sō-lā'nē-ē), *n. pl.* [NL. (Bernard de Jussieu, 1759), < *Solanum* + *-eæ*.] The earliest name for the family *Solanaceæ*, being used by Bernard de Jussieu in his arrangement of the garden of the Trianon: so used also by A. L. de Jussieu, A. P. de Candolle, and others. It has been latterly reduced to tribal rank, and now embraces 36 genera, of which *Solanum* is the type. Among the other most important ones may be mentioned *Lycium*, *Atropa*, *Hyoscyamus*, *Physalis*, *Capsicum*, and *Mandragora*.

solaneous (sō-lā'nē-us), *a.* Belonging to the *Solanaceæ*, or especially to *Solanum*.

solania (sō-lā'ni ä), *n.* [NL., < *Solanum*.] The active principle of *Solanum Dulcamara*. See *solanine*.

solanine (sol'ą-nin), *n.* [NL., < *Solanum* + *-ine*[2].] A complex body, both a glucoside and an alkaloid, the active principle of bittersweet, *Solanum Dulcamara*, and found also in *S. nigrum* and *S. tuberosum*. It is a narcotic poison.

solano (sō-lä'nō), *n.* [< Sp. *solano*, an easterly wind (cf. *solanazo*, a hot easterly wind), < L. *solanus* (sc. *ventus*), the east wind, < *sol*, sun: see *sol*[1], *solar*[1].] A hot (also a rainy) easterly wind on the eastern coast of Spain; hence, a steady wind blowing over a broad expanse of country, such as the pampero or the norther.

solanoid (sol'ą-noid), *a.* [< NL. *Solanum* + Gr. εἶδος, form.] Resembling a potato in texture.

Solanum (sō-lā'num), *n.* [NL. (Tournefort, 1700), < LL. *solanum*, the nightshade.] A genus of dicotyledonous sympetalous plants, type of the *Solanaceæ*, or nightshade family, and tribe *Solaneæ*. It is characterized by flowers usually with a deeply five- or ten-lobed spreading calyx, an angled or five-lobed wheel-shaped corolla, very short filaments with long anthers which form a cone or cylinder, open by a vertical pore or a larger chink, and are almost destitute of any connective, and a generally two-celled ovary with its conspicuous placentæ projecting from the partition. It is one of the largest genera of plants (compare *Senecio*), and includes over 900 species (about 1,200 according to some authors). Their distribution is similar to that of the family, and they constitute half or two thirds of its species. They are herbs, shrubs, or small trees, sometimes climbers, of polymorphous habit, either smooth, downy, or woolly, or even viscous. They bear alternate entire or divided leaves, sometimes in pairs, but never truly opposite. Their flowers are yellow, white, violet, or purplish, grouped in panicled or umbeled cymes which are usually scorpioid, sometimes apparently racemose, rarely reduced to a single flower. The species form four groups, the sections *Pachystemonum*, *Leptostemonum*, *Lycianthes*, and *Nycterium*, based mainly on differences in the calyx, corolla, and anthers, and whether armed with spines or unarmed. South America is the central home of the genus, and of its most useful member, the potato, *S. tuberosum*, which occurs in numerous wild varieties, with or without small tubers on the rootstocks, from Lima to latitude 45° S. in Patagonia, and northward to New Mexico. (See *potato*, *potato-rot*, and cuts under *rotate* and *tuber*.) There are eighteen native species in the United States, chiefly in the southwest, besides numerous prominent varieties and 5 introduced species. The seeds of many species are remarkably tenacious of life, and are therefore soon naturalized, especially the cosmopolitan weed *S. nigrum*, the common or black nightshade, the original type of the genus (for which see *nightshade*, and figure of leaf under *repand;* and compare *ointment of poplar-buds*, under *ointment*): from this the name *nightshade*

is sometimes extended to several other European species. For *S. Dulcamara*, the bittersweet, the other common species of the northeastern United States, a climber introduced for ornament, see *nightshade, felonwort, dulcamara*, and *dulcamarin*. Two others in the United States are of importance as prickly weeds, *S. Carolinense* (for which see *horse-nettle*), a pest which has sometimes caused fields in Delaware to be abandoned, and *S. rostratum* (for which see *sand-bur*), of abundant growth on the plains beyond the Mississippi, and known as the chief food of the Colorado beetle or potato-bug before the introduction of the potato westward. The genus is one of strongly marked properties. A few species with comparatively inert foliage have been used as salads, as *S. Desvauxii* in the West Indies and *S. sessiliflorum* in Brazil; but the leaves of most, as of the common potato, bittersweet, and nightshade, are more or less powerfully narcotic. (See *solanine*.) The roots, leaves, seeds, and fruit-juices yield numerous remedies of the tropics. *S. jubatum* is strongly sudorific; *S. pseudoquina* is a source of quina in Brazil, a powerful bitter and febrifuge; others are purgative or diuretic, as *S. paniculatum*, the jerubeba of Brazil; *S. stramonifolium* is used as a poison in Cayenne. The berries are often edible, as in the well-known *S. Melongena* (for which see *egg-plant, brinjal*, and *aubergine*). Others with edible fruit are *S. aviculare* (known as the *kangaroo-apple* or *gunyang* of southeastern Australia), *S. Uporo*, the cannibal-apple or borodina of the Fiji and other Pacific islands, with large red fruit used like the tomato, *S. album* and *S. Æthiopicum*, cultivated in China and southern Asia, *S. Gilo* in tropical America, *S. muricatum*, the pepino or melon-pear of Peru, and *S. racemosum* in the West Indies. *S. Quitoense*, the Quito orange, yields a fruit resembling a small orange in color, fragrance, and taste. *S. Indicum* is known as *Madagascar potato*, and *S. crispum* of Chile as *potato-tree*. Some species bear an inedible fruit, as *S. mammosum*, the macaw-bush (which see), also called *susumber* and (together with *S. torvum*) *turkey-berry*. For *S. Bahamense*, see *cankerberry*, and for *S. Sodomæum*, see *Sodom-apple*, 2. Other species yield dyes, as *S. gnaphaloides* in Peru and *S. Vespertilio* in the Canaries, used to paint the face; *S. nigrum*, used to dye silk violet; and *S. indigoferum*, in cultivation in Brazil for indigo. *S. marginatum* is used in Abyssinia to tan leather; and the fruit of *S. saponaceum* is used as soap in Peru. Several species have long been cultivated as ornaments for their abundant red or orange berries, as *S. Pseudocapsicum*, the Jerusalem cherry or winter-cherry (see *cherry*[1]), and the Brazilian *S. Capsicastrum*, the dwarf winter-cherry or star-capsicum. Many others are now cultivated as ornamental plants, and are known by the generic name *Solanum*, as *S. Karstenii*, from Venezuela, with violet flowers; and *S. lanceolatum*, with narrow willow-like leaves, reputed the most showy blooming species. Others are cultivated for their conspicuous foliage, as *S. crinitum* and *S. macranthum*, with leaves 2½ feet long; *S. robustum*, clad in showy red down; and *S. Warszewiczii*, with handsome flowers and large leaves elegantly cut. The climber *S. jasminoides*, the jasmine-solanum, is a house-plant from Brazil, esteemed for its large and abundant clusters of fragrant white or bluish flowers.

Being melted on each surface, the solder, partly by chemical attraction and partly by cohesive force, binds them together. After cleaning the edges to be joined, the workman applies a solution of zinc in hydrochloric acid and also powdered rosin to the cleaned surfaces; then he touches the heated soldering-iron to the rosin, and holding the solder-bar and iron over the parts to be joined melts off little drops of solder at intervals along the margins, and runs all together with the hot iron. There are many of these alloys, as soft solder used for tinware, hard solder for brass and iron, gold solder, silver solder, spelter solder, plumbers' solder, etc. Every kind is used at its own melting-point, which must always be lower than that of the metals to be united, soft solders being the most fusible.

Cf. *soil*[1], *sole*[2].] **1.** The bottom or under side of the foot; technically, the planta, corresponding to the palm of the hand. The *sole* of ordinary language does not correspond well with *planta,* except in the cases of plantigrades. In digitigrades *sole* usually means only that part of the planta which rests upon the ground in ordinary locomotion, or the balls of the toes collectively; it also applies to the fore as well as the hind feet of such quadrupeds, thus including the corresponding parts of the *palma,* or palm; while the planta may extend far up the hind leg (only), as to the hock of the horse. In the horse *sole* is restricted to the under side of the hoof of either fore or hind feet (see def. 4 (*b*)). In birds the *sole* of the foot is the under side of the toes taken together. See *planta,* and cuts under *plantigrade, digitigrade, scutelliplantar,* and *solidungulate.*

compared to the form of a human sole; the dorsal and anal fins are very long, but free from the caudal, which has a rounded end, and pectorals are developed on both sides; the mouth is moderately decurved; the nostrils of the blind side are not dilated; and the height of the body is a little less than a third of the total length. The color is a dark brown, with a black spot at the end of the pectoral fin. This sole is common along the European coasts, and is one of the most esteemed of food-fishes. The flesh is white, firm, and of excellent flavor, especially when the fish has been taken in deep water. The average weight is about a pound, although the fish occasionally reaches a much larger size. It prefers sandy or gravelly shores, but retires into deep water when frost sets in. It feeds chiefly upon mollusks, but also on the eggs of fishes and other animals. It sometimes ascends into fresh water. There are other species, of several different genera, as *Achirus lineatus,* commonly called *hog-choker.* The name *sole* is also given to various species of the related family *Pleuronectidæ.* Along the Californian coast the common sole is a pleuronectoid, *Eopsetta jordani,* which reaches a length of about 20 inches and a weight of five or six pounds, although its average weight as seen in the markets is about three pounds. In San Francisco only about two per cent. of the flatfishes caught belong to this species, but along Puget Sound it constitutes about thirty per cent. of the catch. It feeds chiefly on crustaceans and small fishes, and is regarded as an excellent food-fish. Other *Pleuronectidæ* called *soles* along the Pacific coast of North America are the *Parophrys vetulus* and *Lepidopsetta bilineata.* See also cuts under *Pleuronectidæ* and *Soleidæ.*

3. An advocate; specifically, one who represents a party in a court of justice, particularly a court of equity. Generally, in the United States, wherever the distinction between courts of law and of equity remains, practitioners in the latter are termed *solicitors*. In England solicitors are officers of the supreme court, and the medium between barristers and the general public; they prepare causes for the barrister, and have a right of audience as advocates before magistrates at petty sessions, at quarter-sessions where there is no bar, in county courts, and in the bankruptcy court, but they cannot appear as advocates in any of the superior courts, or at assizes, or at any court of commission. Solicitors were at one time officers only of the court of chancery, but the term is now applied to all attorneys. In Scotland solicitors are of two classes—solicitors in the supreme court, who occupy a position similar to that of solicitors in England; and solicitors at law, who are members of a society of law-agents at Edinburgh, incorporated by royal charter and entitled to practise before inferior courts; they are also known by the name of *procurators*. Law-agents of both kinds in Scotland are now on an equal footing. *Slater.*

=Syn. 1. Dense.—8. Stable, weighty, important.

II. *n.* **1.** A body which throughout its mass (and not merely at its surface) resists for an indefinite time a sufficiently small force that tends to alter its equilibrium figure, always springing back into shape after the force is removed; a body possessing elasticity of figure. Every such body has limits of elasticity, and, if subjected to a strain exceeding these limits, it takes a set and does not return to its original shape on being let go. This property is called *plasticity*. The minimum energy required to give a set to a body of definite form and size measures its resilience. When the resilience of a body is small and masks its springiness, the body is called *soft*. Even fluids transmit shearing forces if time be allowed, and many substances will yield indefinitely to very small (but not indefinitely small) forces applied for great lengths of time. So solids that have received a small set will sometimes partially recover their figures after a long time. This property in fluids is called *viscosity*, in solids *after-effect* (German *nachwirkung*). The phenomenon is connected with a regrouping of the molecules, and indicates the essential difference between a solid and a liquid. In fluids diffusion is continually active, and in gases it produces phenomena of viscosity. In liquids it is not rapid enough to give rise to sensible viscosity, but the free motion of the molecules makes the body fluid, while the tendency of sets of molecules to continue for a while associated makes the fluidity imperfect. In solids, on the other hand (at least when not under strain), there is no diffusion, and the molecules are consequently in stationary motion or describing quasi-orbits. They thus become grouped in the mode in which they have least positional energy consistent with their kinetic energy. When this grouping is slightly disturbed, it tends to restore itself; but when the disturbance is greater, some of the molecules will tend to return to their old places and others to move on to new situations, and this may give rise to a new permanent grouping, and exhibit the phenomenon of plasticity. But if not quite sufficient for this, disturbances of the molecular motions somewhat similar to the secular perturbations of the planets will result, from which there will be no restoration for a very long time. Solid bodies are very strongly cohesive, showing that the molecules attract one another on the whole; and they are generally capable of crystallization, showing that the attractions of the molecules are different in different directions.

2. In *geom.*, a body or magnitude which has three dimensions—length, breadth, and thickness—being thus distinguished from a *surface*, which has but two dimensions, and from a *line*, which has but one. The boundaries of solids are surfaces. Besides the three round bodies (the sphere, cone, and cylinder), together with the conoids, and the pyramids, prisms, and prismatoids, the most important geometrical solids are the five Platonic and the Kepler-Poinsot regular polyhedra, the two semi-regular solids, and the thirteen Archimedean solids. The faces, edges, or summits of one solid are said to correspond with the faces, edges, or summits of another when the radii from the center of the former to the mid-faces, mid-edges, or summits can be simultaneously brought into coincidence with the radii from the center to the mid-faces, mid-edges, or summits of the latter. If two solids correspond faces to summits, summits to faces, and edges to edges, they are said to be *reciprocal*. If to the edges of one solid correspond the faces or summits of another, while to the faces and summits together of the former correspond the summits or faces of another, the latter is said to be the *summital* or *facial holohedron* of the former. The regular tetrahedron is the reciprocal of itself, and its reciprocal holohedra are the cube and octahedron. The reciprocal holohedra of these, again, are the semi-regular dodecahedron and the cuboctahedron. The facial holohedron of these, again, is the small rhombicuboctahedron. The faces of the truncated cube and truncated octahedron correspond to those of the cuboctahedron. The snub-cube has faces corresponding to the cuboctahedron, and twenty-four faces which in two sets of twelve correspond to the summits of two other cuboctahedra. The faces of the great rhombicuboctahedron correspond to those of the small rhombicuboctahedron. Just as the cube and octahedron are reciprocal, so likewise are the Platonic dodecahedron and icosahedron, though they are related to no hemihedral body like the tetrahedron. Their reciprocal holohedra are the semi-regular triacontahedron and the icosidodecahedron, and the facial holohedron of these, again, is the small rhombicosidodecahedron. The faces of the truncated dodecahedron and truncated icosahedron correspond to those of the icosidodecahedron. The snub-dodecahedron has faces corresponding to those of the icosidodecahedron, and two sets of others corresponding to the summits of two other icosidodecahedra. The faces of the great rhombicosidodecahedron correspond to those of the small rhombicosidodecahedron. The faces, summits, and edges of the great icosahedron and great stellated dodecahedron correspond respectively to the faces, summits, and edges of the Platonic dodecahedron and icosahedron. The great dodecahedron and small stellated dodecahedron are self-reciprocal, both faces and summits corresponding to the faces of the Platonic dodecahedron or summits of the icosahedron. The faces of the truncated tetrahedron correspond to the faces of the octahedron or summits of the cube.

3. *pl.* In *anat.*, all parts of the body which are not fluid: as, the *solids* and fluids of the body. **—4.** *pl.* In *printing*, the parts of an engraving which show black or solid in print.—**Archimedean, rectangular, right solid.** See the adjectives.—**Cissoidal solid,** a solid generated by the rotation of the cissoid about its axis.—**Kepler solid,** or **Kepler-Poinsot solid,** a regular solid which inwraps its center more than once. There are four such solids—the great icosahedron, the great dodecahedron, the small stellated dodecahedron, and the great stellated dodecahedron. Three of them were mentioned by Kepler, and all were rediscovered by Poinsot. The names here used were given by Cayley.—**Logistic solid,** a solid generated by the revolution of a logarithmic curve about its asymptote.—**Plastic solid,** a solid substance whose limit of elasticity is far below its point of rupture, so that it can be shaped: thus, putty and wrought-iron are *plastic solids*.—**Platonic solid,** one of the old regular solids which inwrap the center only once. They are five—the tetrahedron, the cube, the octahedron, the twenty-vertexed dodecahedron, and the icosahedron.—**Regular solid,** a polyhedron whose faces are regular polygons, all alike.—**Semi-regular solid,** a body whose edges are all of equal length, whose faces are all alike and equally incline to one another at the edges, but whose faces are not regular polygons. Two such solids are known—the rhombic dodecahedron and triacontahedron.—**Solid of least resistance.** See *resistance*.—**Solid of revolution.** See *revolution*.

Solidago (sol-i-dā′gō), *n.* [NL. (Vaillant, 1720), < ML. *solidago*, goldenrod (*Solidago Virgaurea*), so called from its reputed vulnerary qualities, < L. *solidus*, solid: see *solid*.] **1.** A genus of composite plants, the goldenrods, belonging to the tribe *Astereæ* and to the subtribe *Solidagininæ*. It is characterized by several-flowered small and radiate yellow heads, with a small flat usually alveolate receptacle, and an oblong involucre of erect rigid bracts which are closely imbricated in several rows and are without herbaceous tips. The oblong or obovoid five- to twelve-ribbed achenes bear a copious whitish pappus of long and nearly equal slender bristles. From *Aster*, which it closely resembles in technical characters, it is distinguished by its taller wand-like habit, yellow rays, smaller heads, and the absence of cordate leaves; from *Chrysopsis* and *Pyrrocoma* by its narrow few-flowered heads; and from *Chrysothamnus*, another important near relative, by the presence of rays. The species have in general a very characteristic habit, being perennial herbs, usually with strictly erect unbranched stems, which bear numerous entire or serrate alternate sessile narrow stem-leaves and broader root-leaves, which taper into margined petioles. Numerous intermediate forms render many species difficult to distinguish. In the original species, *S. Virgaurea*, the golden-yellow flowers are massed in small clusters which form an elongated or interrupted spike, whence the popular name *goldenrod*. The typical inflorescence, however, is a terminal pyramidal panicle of determinate development, composed of numerous recurving and scorpioid one-sided racemes, best seen in *S. Canadensis* and *S. rugosa*. In other species the flowers form a dense thyrsus of straight and terete crowded racemes, as *S. speciosa*, of the Atlantic and interior United States. A few others from the Ohio and Mississippi valleys, as *S. rigida*, produce nearly level-topped cymes. Four other cymose species formerly referred here are now separated as a genus, *Euthamia* (Nuttall, 1818), distinguished by lack of scorpioid branchlets and by their linear entire one- to five-nerved leaves, including the widely distributed species *E. graminifolia* and *E. Caroliniana*, and connecting with *Chrysoma pauciflosculosa*, of the Southern States, separated as a genus because of its shrubby stem and few-flowered heads with one to three rays. Several other species are slightly aberrant: *S. multiradiata*, of the Rocky Mountains, sometimes has twelve rays, others usually five; *S. squarrosa*, of the Eastern States, and *S. petiolaris*, of the Southern States, vary also in the spreading tips of the involucral bracts. *S. bicolor* is remarkable for its cream-colored flowers. *S. verna*, of pine-woods near Wilmington, North Carolina, blooms in May; *S. uliginosa*, of northern peat-bogs, in July; *S. juncea* and *S. Elliottii* in August; and *S. rugosa*, *S. Canadensis*, and most others mainly in September; *S. nemoralis* and *S. cæsia* continue well into October. The genus is one of the most characteristic of the United States, numerous both in species and in individuals, and not entirely wanting in any region. In the northern and central States it gives to the landscape much of its beauty, and is an important element of the prevailing yellow of autumn. There are more than 100 species, nearly all of which are natives of the United States, and the others are mostly American, 9 of them occurring in Mexico, 2, 3, or 5 in South America (3 in southern Brazil, 2 in Uruguay, and 1 in Chile), and 1 in Hayti. Only 3 species are natives of the old world, *S. alpestris* and *S. littoralis*, limited to the Tuscan and Ligurian coast, and *S. Virgaurea*, which extends from Mount Parnassus north and west throughout Europe and into Siberia, Alaska, New York, and New England, in many widely differing forms. Those of the United States are all, with 6 exceptions, confined to them and to British America (into which 32 extend), and are mainly natives of the Atlantic and central States. Numerous isolated species are southern; the northern are mostly of wider distribution and more abundant in individuals; 11 species are mainly confined to the high northern, 7 to the northeastern, 43 to the southern, 6 to the southwestern, 8 to the Pacific States; 6 belong to the Mississippi valley, of which *S. Missouriensis* is the only one widely distributed; 2 species, *S. odora* and *S. sempervirens*, extend throughout the Atlantic coast from Canada to Mexico, and the latter, the salt-marsh goldenrod, reappears in the Azores and at San Francisco. Forty-eight species occur in the northeastern United States, 74 in the Southern States, and about 14 among the Rocky Mountains. *S. Canadensis*, the most numerous and most typical species, is also the one most widely diffused (through the United States, followed next by *S. nemoralis* and *S. rugosa*. The species of this genus range from beyond 66° N. latitude to the city of Mexico, and from alpine summits to the sea-level; several are mostly confined to swamps, as *S. patula*, and a few to woodland borders, as *S. cæsia* and *S. bicolor*, but most are plants of dry open soil, especially *S. nemoralis*. In parts of the Atlantic coast the name *goldenrod* is locally confined to *S. odora*, the sweet goldenrod of authors, which contains in its dotted leaves an aromatic and stimulating volatile oil of an anisate odor and pale greenish-yellow color; it is also carminative and diaphoretic, and its infusion is used to relieve spasmodic pains and nausea; its dried flowers and leaves have been employed as a beverage, under the name of *Blue-Mountain tea*. *S. Virgaurea*, the goldenrod of Europe, contains an astringent and tonic principle, and was long in esteem for healing wounds,

herbalists of two and three centuries ago pronouncing it "one of the most noble wound-herbs," and prescribing "a tea of the young leaves, green or dry.' It was also once in repute in Europe as a dye, and a variety of *S. nemoralis* is locally called *dyer's-weed* in America. *S. Canadensis* and others have been popularly known as *yellow-weed*, and *S. rugosa* as *bitterweed*. *S. rigida* is also a reputed astringent. The goldenrod has been recommended by many as the national emblem of the United States.

2. [*l. c.*] A plant of this genus; goldenrod.

solmizate (sol′mi-zāt), *v. i.*; pret. and pp. *solmizated*, ppr. *solmizating.* [< F. *solmiser* (as *sol* + *mi*, notes of the gamut (cf. *sol-fa*), + *-iser* = E. *-ize*), + *-ate*[2].] In *music*, to use solmization syllables. Also spelled *solmisate.*

solmization (sol-mi-zā′shọn), *n.* [< F. *solmisation;* as *solmizate* + *-ion.* Cf. ML. *solmifacio(n-).*] In *music*, the act, process, or result of using certain syllables to name or represent the tones of the scale, or of a particular series, as the scale of C. The oldest and most important system of solmization is that attributed to Guido d'Arezzo, early in the eleventh century; though this in turn appears to have been suggested by a similar usage among the ancient Greeks. (See *gamut.*) The series *ut, re, mi, fa, sol, la* (derived from the initial syllables of the lines of a hymn to St. John, beginning "Ut queant laxis") was applied to the tones of each of the hexachords then recognized. (See *hexachord.*) When a melody exceeded the limits of a single hexachord, a change from one series of syllables to another was made, which was called a *mutation* or *modulation.* Early in the sixteenth century, when the modern octave scale became established, the syllable *si* (probably taken from the initials of the last line of the above hymn) was added for the seventh or leading tone. Somewhat later *do* was substituted in Italy and Germany for *ut*, on account of its greater sonority. The series thus formed is still in use, though other systems have been proposed. Such other systems are *bocedization* (*bo, ce, di, ga, lo, ma, ni*), also called *bobization; bebization* (*la, be, ce, de, me, fe, ge*); and *damenization* (*da, me, ni, po, tu, la, be*). In England and America, from before the middle of the seventeenth century to the beginning of the nineteenth, an abbreviated system was used, including only *mi, fa, sol, la.* The ideal application of solmization involves calling whatever tone is taken as the key-note *do*, irrespective of its pitch, and adjusting the other syllables accordingly, so that the scale-tones shall always be named by the same syllables respectively, and the various intervals by the same combination of syllables. This system is often called that of the *movable do*, since the pitch of *do* is variable. What is called the *fixed-do system* has also had considerable currency in Italy, France, and England, according to which the tone C is always called *do*, D *re*, E *mi*, etc., and this too when the pitch of these tones is chromatically altered, the system therefore following the arbitrary features of the keyboard and the staff-notation. This system is regarded by many musicians as contrary to the historic and logical idea of solmization, and its use in England and America is decreasing. The most important special application of solmization in musical study is that of the *tonic sol-fa system* (which see, under *tonic*), the syllables of which are *doh, ray, me, fah, soh, lah, te.* In the *movable-do system* the sharp of any tone is indicated by a syllable beginning with the same consonant as that of the tone, and using the vowel *i:* as, *di* for *do♯, fi* for *fa♯*, etc.; and similarly the flat of any tone is indicated by a syllable using the vowel *e:* as, *me* for *mi♭, le* for *la♭*, etc. The minor scale is solmizated in two ways: either beginning with *la*, and using the same syllables as in the major scale; or beginning with *do*, and using such modified syllables as may be needed (*do, re, me*, etc.). The great utility of solmization lies in its offering an abstract vocal notation of musical facts, whereby they may be named, remembered, and studied. ★Also *solmisation, solfamization, solfeggio*, and *sol-faing.*

solo (sō′lō), *a.* and *n.* [< It. *solo*, alone, < L. *solus*, sole: see *sole*[3].] **I.** *a.* In *music*, alone; not combined with other voices or instruments of equal importance; not concerted. A solo passage may be accompanied, however, by voices or instruments of less importance.—**Solo organ**, in *organ-building*, a partial organ introduced into large instruments, containing stops of special power or effectiveness, such as are used in producing striking solo effects. Its keyboard is usually the upper one when there are four, or the lower when there are three. Its stops are often connected with a special bellows, which is weighted with extra weights; they are then said to be "on a heavy wind." The choir-organ is also sometimes loosely called the *solo organ.* See *organ*[1].—**Solo pitch**, in *music*, a special pitch or accordatura (scordatura) adopted by a solo performer upon a violin or other solo instrument, so as to produce peculiar and startling effects.—**Solo stop**, in *organ-building*, a stop either of special quality or placed on a heavy wind, so as to be fitted for the performance of solos. Such stops often occur in each of the usual partial organs, but in large instruments the most important of them are gathered into a separate partial organ called the *solo organ* (see above).

The act of separating the parts of any body; disruption; rupture; fracture; breach: as, a *solution* of continuity (see below).—2. A physically homogeneous liquid or solid mixture of two or more chemical substances; a preparation made by dissolving a solid, liquid, or gaseous substance in another substance, commonly a liquid. The constituent present in largest proportion is called the *solvent*, and is usually a liquid, though in special cases it may be a solid. The dissolved substance or *solute* may be solid, liquid, or gaseous: as in solutions of salt, acetic acid, or ammonia in water. Solid solutions are exemplified by the mixture produced by absorbing hydrogen in palladium, by many homogeneous alloys, and by mixtures of isomorphous crystalline substances. Mixtures of gases, in which each constituent still exhibits all its characteristic properties, are not commonly regarded as solutions.

By a study of the molecular conductivity of dilute *solutions* of different salts containing a common anion, . . . Kohlrausch was led to the conclusion that the maximum molecular conductivity of an electrolyte can be calculated by adding together two constants, the values of which depend on the nature of the anion and kation respectively. *W. Watson*, Text-book of Physics, p. 805.

3. The act or process by which two or more substances unite to form a single homogeneous liquid or solid mixture; the conversion of a substance from the solid or gaseous to the liquid state by treatment with a liquid. When the substances can be recovered from the solution in their original form by evaporation or other physical process, the process is said to be a *simple* or *physical solution*, such as the dissolving of sugar in water, or of gold in mercury. When, however, a new chemical substance results and can be isolated by removal of the solvent, the process is said to be a *chemical solution*, as the dissolving of silver in nitric acid. The physical solution of gases in liquids is always, and that of liquids in liquids is usually, attended by an evolution of heat; that of solids in liquids is commonly, but not invariably, accompanied by an absorption of heat. A chemical solution almost always gives rise to an evolution of heat. It is probable that in many cases of so-called physical solution a chemical compound is formed by union of the solvent with the dissolved substance.

4. A liquid or dissolved state or condition; unsettled state; suspense.

His [Lessing's] was a mind always in *solution*, which the divine order of things, as it is called, could not precipitate into any of the traditional forms of crystallization, and in which the time to come was already fermenting.

The somatopleure thus constitutes usually the great mass of the body, or the "flesh and bones" of ordinary language, together with its vessels, nerves, and other special structures — not, however, including the cerebrospinal axis of a vertebrate, which is derived from an inversion of ectoderm — while the splanchnopleure forms a portion of the substance of the intestinal tract and its annexes. This influence is not wholly due to the mere physical attraction between them, but is the result of a stimulating effect on what has been called the *nervimotility* of the organ. Growing organs may be divided, according to their response to this influence, into two classes, the *positively somatotropic*, or those which tend to grow perpendicularly inward into the substratum, and *negatively somatotropic*, or those which tend to grow perpendicularly outward from the substratum.

3. In *logic*, at least one, perhaps all; but a few logicians sometimes employ a semidefinite *some* which implies a part, but not all. As commonly used in logic, a statement about *some* of a class, say that "some S is P," means that it is possible so to select an S that it shall be P; while "every S is P" means that whatever S be taken, it will be P. But when *some* and *every* occur in the same statement, it makes a difference which is chosen first. Thus, "every man knows some fact" may mean (1) that, first choosing any man, a fact may then be found which that man knows (which may be expressed by saying that every man knows some fact or other); or it may mean (2) that a fact may be first selected such that, then, taking any man, he will know that fact (which may be expressed by saying that all men know some certain fact). When several *somes* and *alls* occur in the same statement, ordinary syntax fails to express the meaning with precision, and logicians resort to a special notation.

somital (sō′mi-tạl), *a.* [< *somite* + *-al.*] Same as *somitic.*

somite (sō′mīt), *n.* [< Gr. *σῶμα*, body, + *-ite*[2].] An actual somatome; any one morphological segment of an articulated body, such a body being viewed as composed of a longitudinal series of somites; an arthromere or metamere of an articulate invertebrate or a diarthromere of a vertebrate; such a segment considered with or without the appendages it may possess; in the latter restricted sense, a metamere minus its appendages, or a segment of the soma or trunk without the limbs it may bear. The term sometimes extends to ideal somatomes, or to the metameres of which an organism is theoretically assumed to consist; but it is especially applied to the actual segments of such invertebrates as insects, crustaceans, and worms, whose body-rings are usually evident, though some or other of them may coalesce, as into a cephalothorax, etc. In such cases the primitive or morphological somites are usually recognized and reckoned by their respective pairs of appendages. Separate somites, continued throughout the body, are evident in the rings of earthworms and other annelids. In arthropods the typical number of somites is supposed to be twenty or twenty-one, numbers often actually recognizable. In insects the head is assumed to have six or seven somites, the thorax has normally three (see *prothorax*, *mesothorax*, and *metathorax*), and the abdomen is supposed to have ten or eleven. Each of these somites is invested and indicated by a body-ring or crust of integument, primitively or typically composed of eight sclerites, which may variously coalesce with one another, or with pieces of another somite, or both. Those sclerites which ordinarily remain distinct, and thus can be identified, take special names, as *tergite*, *pleurite*, *sternite*, *scutum*, *præscutum*, etc., *epimeron*, *epipleuron*, etc. Appendages of somites are limbs in the broadest sense, under whatever modifications; and these modifications are usually greatest at the cephalic and caudal ends of the body, as into eyestalks, antennæ, palpi, mandibles, maxillæ, maxillipeds or gnathopodites, etc., of the head, and stings, claspers, or other anal armature. Intermediate somitic appendages are ordinary legs and wings, as of the thorax of insects, and the pereiopods, pleopods, chelæ, rhipidura, telson, etc., of the thorax and abdomen of crustaceans. In worms such appendages chiefly occur in the form of parapodia (neuropodia and notopodia). See *sclerite*, and cuts under *Amphithoë*, *Apus*, *Buthus*, *Scorpionidæ*, *Blattidæ*, and *cockroach.*

somitic (sō-mit′ik), *a.* [< *somite* + *-ic.*] Having the character of a somite; somatomic; metameric; of or pertaining to somites: as, the *somitic* divisions of the body; a *somitic* ring or joint; a *somitic* appendage.

The sleeping condition is shown by the absence of the usual reaction to sense-impressions, and usually by the failure to recall what has been done during the somnambulistic period. With many recent writers, however, the word is used, quite independently of any consideration of movements which the somnambulist may or does execute, as nearly synonymous with *trance*, *mesmerization*, or *hypnotism*, and exactly so with *somnolism.* It is generally considered under the two main conditions of the idiopathic, spontaneous, or self-induced and the artificial or induced. Compare *somnolism.* Also called, rarely, *noctambulism.*

In *somnambulism*, natural or induced, there is often a great display of intellectual activity, followed by complete oblivion of all that has passed.

Specifically—**2.** A short poem in fixed form, limited to fourteen lines with a prescribed disposition of rimes. The form is of Italian origin. A sonnet is generally written in decasyllabic or five-foot measure; but it may be written in octosyllabics. It consists of two divisions or groups of lines—(1) a major group of eight lines or two quatrains, and (2) a minor group of six lines or two tercets. The quatrains are arranged thus: *a, b, b, a; a, b, b, a;* the tercets, either *c, d, c, d, c, d,* or *c, d, e, c, d, e.* In modern French examples the order of the tercets is generally *c, c, d, e, d, e.* There are various deviations from the sonnet as thus described; but by purists the above is regarded as the orthodox form, established by long practice and prescription, all others being ranked simply as quatorzains, or what Lamb called *fourteeners.* With regard to the material of the poem, it is generally considered that it should be the expression of a single thought, idea, or sentiment.

(Linnæus, 1737), < Ar. *sofāra*, a yellow plant (applied to one faded), < *asfar*, yellow: see *saffron*.] A genus of leguminous plants, of the family *Fabaceæ*, type of the tribe *Sophoreæ*. It is characterized by flowers with a broadly obovate or orbicular banner-petal and oblong wings and keel, grouped in terminal racemes or panicles, and followed by thick or roundish or four-winged pods which are constricted into a succession of necklace-like joints (see cut under *moniliform*), and are usually indehiscent. There are about 25 species, natives of warm regions of both hemispheres. They are trees and shrubs, rarely perennial herbs, and bear odd-pinnate leaves, usually with very numerous small leaflets, but sometimes only a few, and then large and rigid. The flowers are white, yellow, or violet, and highly ornamental. Six species occur within the United States: *S. secundiflora*, the coral-bean of Texas (see *frigolito*); *S. affinis*, a small tree of Arkansas and Texas, with hard, heavy, coarse-grained, yellow and finally red wood, and resinous pods, from which a domestic ink is made; and *S. tomentosa*, a shrub of the Florida coast, with showy yellow flowers, also widely distributed along tropical shores of Amer-

Japonica* is the Chinese or Japanese pagoda-tree or yenju, a very handsome quick-growing tree reaching 60 feet in height, with dark-green younger branches and deep blue-green leaves, sometimes cultivated, especially for its large panicles of small whitish autumnal flowers. Its hard compact wood is valued for turners' work; all parts are purgative; the austere pulp of the pods dyes yellow; and the flowers (called in Chinese *wai-fa*) furnish a yellow dye greatly valued in China. For this the tree is cultivated in several provinces, from which the dried flowers are exported in small sacks and used to dye blue cloth green, and to dye yellow the silk garments of the mandarins and the rush-mats which form the Chinese sails, beds, bags, and floor-matting.

Such cells form little heaps or cushion-like masses breaking through the surface of the thallus, and when set free from the thallus are able to grow at once into new thalli. Usually one species of alga furnishes all the algal cells of a lichen; more rarely two, and then one prevails in abundance over the other. The same species of alga, however, may be found in consortism with different species of fungus, and taking part in the composition, therefore, of differently formed thalli—that is, different lichens. They have from 28 to 32 colored teeth, moderately long well-haired tail and ears, and feet not oared. The typical dentition of *Sorex* in the most restricted sense is 32 teeth, of which the upper incisors are 8, the (unspecialized canines and) upper premolars 6, the upper molars 6, and the total of the lower teeth 12 (as nearly constant throughout the family). *S. vulgaris* is the common shrew found in Europe, and *S. personatus* is a common one in North America. See *shrew*[2].

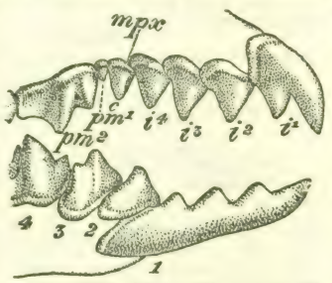
Pg. *sorgo* = It. *sorgo, surgo;* < NL. *sorgum, sorghum*, < ML. *surgum, surcum, suricum*, Indian millet, sorghum; prob. of E. Ind. origin.] **1.** A plant of the proposed genus *Sorghum*, commonly the cultivated saccharine plant once known as *Sorghum* (or *Holcus*) *saccharatum*, but now classified as *Andropogon Sorghum*, or as a variety of that species. It is a cane-like grass, with the stature and habit of broom-corn, or of the taller varieties of Indian corn, but more slender than the latter, without ears, and of a glaucous hue. Sorghum is cultivated throughout Africa, in forms called *imphee*, chiefly for the sweet juice of the cane. In the United States it has been employed for many years to make syrup, for which purpose it is more or less grown in every State. It has also been the subject of much experiment in sugar-making, but the product is too costly. It is a valuable forage plant extensively used in some sections for silage. The name is also applied to *Andropogon Halepensis*, and possibly to others of the same genus.

2. [*cap.*] [NL. (Micheli, 1729).] A proposed genus of grasses, of the tribe *Andropogoneæ*, by most authors included as a subgenus in *Andropogon*. Like the rest of the genus, it has one-flowered spikelets disposed in pairs at the joints of a rachis, one of each pair pedicelled, one sessile. The sessile spikelet is in all the pairs alike; the flower is fertile, and in the pedicelled spikelets male, neutral, or abortive. The rachis is fragile, or in culture tenacious; its joints and the pedicels are filiform, and convex on the back or flat without furrow. The sessile spikelet and grain are somewhat compressed on the back, or in cultivation sometimes nearly globose. The species are most often tall and flat-leaved grasses, diffused through the tropics and here and there in the temperate zone—one, *Andropogon Halepensis*, the Johnson grass, is a stout perennial much grown for hay in the Southern States, where it makes a very rapid growth. When once established it is difficult to eradicate and has become a very troublesome weed in some sections. It is much admired in Europe as an ornamental grass and is sometimes cultivated in the north for that purpose. The most important species is *A. Sorghum*, a polymorphous much-cultivated species. Hackel divides it into the following varieties: the broom-corn (var. *technicus*), in which the branches of the panicle are elongated and are thus adapted to the manufacture of brooms; the sorghum (var. *saccharatus:* see def. 1); the durra (vars. *cernuus* and *Durra*), the so-called Indian or African millet (covering perhaps the last and the var. *vulgaris*); and the guinea-corn or Kafir-corn, if it is different from the durra. The Johnson grass is also called *Egyptian, Cuba*, or *Guinea grass, Australian* or *Morocco millet*, etc., and *sorghum*. The durra has been somewhat cultivated in the United States, some forms of it being called *Millo maize*. See *broom-corn, durra*, and *Indian millet* (under *millet*).

Sorghum (*Andropogon Sorghum*). 1, wild form; 2, panicle of same; *a*, spikelets of cultivated form.



sorgo (sôr'gō), *n.* Same as *sorghum*.

sori, *n.* Plural of *sorus*.

Soricidæ (sō-ris'i-dē), *n. pl.* [NL., < *Sorex* (*Soric-*) + *-idæ*.] A family of small insectivorous mammals, the shrews. They are of terrestrial, sometimes natatorial, habits, with a long and narrow skull without zygomatic arches or postorbital processes, annular tympanic bones, no symphysis pubis, the fore limbs not specially modified as in the moles, the tibia and fibula united, and the lower teeth 12 (in one genus 12

or 14). The lower incisors are long, proclivous, and usually notched; in the upper teeth the median incisors are large, and have a basal snag or cusp, appearing as if double (but see *soricident*); no canines are specialized, and the premolars are variable; the molars are large and multicuspidate. The total number of the teeth varies from twenty-six to thirty-two. The family is well marked, with little range of variation, though the species are so numerous. The shrews are all small animals, some being the smallest known mammals, and have the general appearance of mice, though with more pointed snout. The rather numerous (about 12) genera fall in two groups or subfamilies, *Soricinæ* and *Crocidurinæ*.

soricident (sō-ris'i-dent), *a.* [< L. *sorex* (*soric-*), a shrew, + *den*(*t-*)*s* = E. *tooth*.] Having or noting a dentition like that of shrews. This dentition is unique in some respects. It consists of the four kinds of teeth usual among diphyodont mammals, but no canines are specialized as such, and the median pair of incisors both above and below are remarkable in presenting two or more cusps, besides being of great size. These peculiarities, together with the speedy and complete obliteration of the maxillopremaxillary suture, have caused the median incisors alone to be so named, and have occasioned great uncertainty in the dental formulæ of the several genera of shrews. Determination of the position of the suture has shown, however, that several other pairs of teeth besides the specialized median upper pair are inserted in the premaxillary, and are therefore incisors; that the foremost pair of maxillary teeth (technically canines) are never specialized, and always small, and that these are followed by one or two pairs of premolars, constantly succeeded by three pairs of true molars. The constancy in number of the under teeth (twelve, with some anomalous exceptions) is also remarkable, and the total variation is only from twenty-six to thirty-two among all the genera. The eight upper incisors of several genera are a number unique among placental mammals; and the soricident dentition is, on the whole, in proportion to the size of the animals, the most formidable known among mammals, of greater relative power than that of any carnivore. See *Soricidæ*.

Soricident Teeth of Common Shrew (*Sorex vulgaris*), enlarged seven times.

i^1, large two-pronged anterior upper incisor; i^2, i^3, i^4, succeeding upper incisors, to *mpx*, line of obliterated maxillopremaxillary suture; *c*, first maxillary tooth, technically a canine, unspecialized and resembling the preceding incisor; pm^1, minute first premolar; pm^2, large sectorial premolar. In the lower jaw, 1, very large serrated anterior incisor; 2, second incisor; 3, fourth premolar; 4, first molar.

Soricinæ (sor-i-sī'nē), *n. pl.* [NL., < *Sorex* (*Soric-*) + *-inæ*.] The typical subfamily of *Soricidæ*, containing those shrews of both the Old and the New World which have the teeth brown or red: contrasted with *Crocidurinæ*. The genera usually admitted are *Sorex*, *Neosorex*, *Notiosorex*, *Soriculus*, *Blarina*, and *Crossopus*. See *Sorex*, and cuts under *Blarina*, *shrew*, and *sondeli*.

In def. 2 first used by Laurentius Valla (died 1457).] **1.** A kind of sophism invented by Chrysippus in the third century before Christ, by which a person is led by gradual steps from maintaining what is manifestly true to admitting what is manifestly false. Gr. *ψυχή*, etc.); origin unknown. The word has been compared with Gr. *αἰόλος*, quick-moving, changeful, and with *sea* (see *sea*[1]); also with L. *sæculum*, age (life, vitality ?) (see *secle, secular*).] **1.** A substantial entity believed to be that in each person which lives, feels, thinks, and wills. Animals also, and even plants, have been thought to have souls. Primitive peoples identify the soul with the breath, or something contained in the blood. Separated from the body, it is supposed to have some imperfect existence, and to retain the form of the body as a ghost. The verses of Davies (see below) enumerate most of the ancient Greek opinions. The first is that of Anaximander and of Diogenes of Apollonia; the second is that of Heraclitus; the third is that of Empedocles; the fourth is that attributed to Empedocles by Aristotle; the fifth is that of Dicæarchus and other Pythagoreans, as Simmias in the "Phædo"; the sixth is attributed wrongly to Galen; the seventh is that of Democritus and the atomists; the eighth is attributed by some authorities to the Pythagoreans; and the ninth is that of the Stoics. Aristotle makes the soul little more than a faculty or attribute of the body, and he compares it to the "axness" of an ax. The scholastics combined this idea with that of the separability and immortality of the soul, thus forming a highly metaphysical doctrine. Descartes originated distinct metaphysical dualism, which holds that spirit and matter are two radically different kinds of substance—the former characterized by consciousness, the latter by extension. Most modern philosophers hold to monism in some form, which recognizes only one kind of substance. That the soul is immortal is a very ancient and widely diffused opinion; it is also commonly believed that the soul has no parts. A soul separated from the body is commonly called a *spirit*, not a *soul*. In biblical and theological usage 'soul' (*nephesh, psyche*, also rendered 'life') is sometimes used for the noncorporeal nature of man in general, and sometimes, in distinction from *spirit*, for the lower part of this non-corporeal nature, standing in direct communication with the body, and regarded as the seat of the emotions, rarely of will or spirit. Some theologians minimize the distinction between *soul* and *spirit*, making them mere aspects or relations of the same substance, while others have made them distinct substances or distinct entities.

For of the *soule* the bodie forme doth take;
For *soule* is forme, and doth the bodie make.

All Souls' day, in the *Rom. Cath. Ch.*, the 2d of November, a day kept in commemoration of all the faithful departed, for the eternal repose of their souls, to which end the mass and offices of the day are directed. It is the day following the feast of All Saints.—**Apparitional soul.** See *apparitional*.—**Commendation of the soul.** See *commendation*, 5.—**Cure of souls.** See *cure*.—**Descent of souls.** See *descent*.—**Seat of the soul,** the part of the body (according to some speculators a mathematical point) in immediate dynamic connection with the soul. As long as the soul was supposed to be a material thing (which was the usual ancient opinion), it was naturally believed to have a distinct place. Later the knowledge of the functions of the nervous system, and their centralization in the brain, showed that the soul was more intimately connected with that than with other parts of the body; and it was vaguely supposed that the unity of consciousness would in some measure be explained by the hypothesis of a special seat of the soul in the brain. The commonest primitive notion was that the soul was resident in the blood or in the heart. Either the whole soul or its parts were also located in the bowels, bones, liver, gall, kidneys, and other organs. The doctrine that the soul is in the brain seems to have originated in Egypt, and found many partial adherents in antiquity, but was not generally accepted before modern times. The Neoplatonists held that the soul is wholly in the whole body and wholly in every part. Descartes placed the soul in the pineal gland, and other physiologists of the seventeenth century located it in different organs connected with the brain. Leibnitz introduced the theory that it resides at a mathematical point, which has found eminent supporters, some of whom regard this point as movable. Others hold that any conception of consciousness which forces its adherents to such a conclusion ought to be considered as reduced to an absurdity. Recent observations concerning multiple consciousness strengthen indications previously known that the unity of consciousness is somewhat illusory; and the anatomy of the brain does not support the notion of an absolute centralization of the power of forming ideas.—**Sentient soul,** the soul as affected by the senses, or as possessing sentience.—**Syn. 1** and **2.** *Intellect, Spirit,* etc. See *mind*[1].—**4.** Ardor, force.

To measure the depth of; fathom; try or test, as the depth of water and the quality of the ground, by sinking a plummet or lead attached to a line on which is marked the number of fathoms. Apparatus used in Sounding.

A, *B*, *C*, Brooke's Deep-sea Sounding-apparatus: *a*, rod with horns *b* pivoted thereto; *c*, sounding-line; *d*, wires by which the lead *e* is attached to the horns, connected with a washer *f* under the lead; *h*, opening in lower end of rod, by which specimens of the bottom may be secured. The cups (shown in the cuts), on closing, scoop up a specimen of the bottom.

strike the ground, and so inclose some of the sand, shells, etc., a cup at the bottom of a long leaden weight, which is closed by a leathern cover when full, etc. See the accompanying cuts of apparatus used in sounding. Brooke's apparatus is said to be the first by which soundings of over 2,000 fathoms were made and specimens of the bottom obtained.

For certes, lord, so sore hath she me wounded
That stood in blake, with lokynge of hire eighen,
That to myn hertis botme it is *ysounded*.
Chaucer, Troilus, ii. 535.

3. To descend to the bottom; dive: said of fish and other marine animals. When a sperm-whale sounds, the fore parts are lifted a little out of water, a strong spout is given, the nose is dipped, the back and small are rounded up, the body bends on a cross-axis, the flukes are thrown up 20 or 30 feet, and the whale goes straight down head first, in less than its own length of water.

Cf. *sound*[5], *v.*, and see *assonant*, *consonant*, *dissonant*, *resonant*, *person*, *parson*, *resound*, *sonata*, *sonnet*, *sonorous*, *sonant*, *unison*, etc.] 1. The sensation produced through the ear, or organ of hearing; in the physical sense, either the vibrations of the sounding-body itself, or those of the air or other medium, which are caused by the sounding-body, and which immediately affect the ear. A musical sound, or *tone*, is produced by a continued and regular series of vibrations (or, in the physical sense, may be said to be these vibrations themselves); while a *noise* is caused either by a single impulse, as an electrical spark, or by a series of impulses following at irregular intervals. A sounding-body is a body which is in such a state of vibration as to produce a sound (see *vibration*). Thus, a tuning-fork, a bell, or a piano-string, if struck, will, in consequence of its elasticity, continue to vibrate for some time, producing, in the proper medium, a sound; similarly, the column of air in an organ-pipe becomes a sounding-body when a current of air is continually forced through the mouthpiece past the lip; again, an inelastic body, as a card, may become a sounding-body if it receives a series of blows at regular intervals and in sufficiently rapid succession, as from the teeth of a revolving cog-wheel. The vibrations of the sounding-body are conveyed to the ear by the intervening medium, which is usually the air, but may be any other gas, a liquid (as water), or an elastic solid. The presence of such a medium is essential, for sound is not propagated in a vacuum. The vibrations of the sounding-body, as a tuning-fork, produce in the medium a series of waves (see *wave*) of condensation and rarefaction, which are propagated in all directions with a velocity depending upon the nature of the medium and its temperature — for example, the velocity of sound in air is about 1,090 feet per second at 32° F. (0° C.), and increases slightly as the temperature rises; in other gases the velocity varies inversely as the square root of the density; it is consequently nearly four times as great in hydrogen. In liquids the velocity is greater than in air — for water, somewhat more than four times as great. In solids the velocity varies very widely, being relatively small in inelastic substances like wax and lead, and very great (two to three miles per second) in wood and steel. Sound-waves may differ (1) in their wave-length — that is, in the number of vibrations per second; (2) in the amplitude of the motion of the particles forming them; and (3) in their form, as to whether they are simple, and consist of a single series of pendulum-like vibrations, or are compound, and formed of several such series superimposed upon each other. Corresponding to these differences in the sound-waves, the sounds perceived by the ear differ in three ways: (1) They differ in *pitch*. If the sound-waves are long and the number of vibrations few per second, the pitch is said to be *low* and the sound is called *grave;* as the number of vibrations increases, the pitch is said to *rise* and the sound to be *higher;* if the number of vibrations is very great and the length of the waves correspondingly small, the sound becomes shrill and piercing. It is found that the vibrations must be as numerous as 24 per second in order that the ear may be able to unite them as a continuous sound. Similarly, if the vibrations exceed 30,000 to 40,000 per second, they cease to produce any sensation upon the ear. (2) Sounds differ in *intensity* or *loudness*. Primarily the intensity of the sound depends upon the amplitude of the vibrations; it diminishes with the square of the distance from the sounding-body; it also diminishes as the density of the air or other medium decreases, and is increased by the proximity of a sonorous body which can vibrate in unison with it. (3) Sounds differ in *quality* or *timbre*, that property by which we distinguish between the same tone as sounded upon two different musical instruments, as a piano and a violin. This difference is due to the fact that a note produced by a musical instrument is in general a compound note, consisting of the fundamental note, the pitch of which the ear perceives, and with it a number of higher notes of small intensity whose vibrations as compared with the fundamental note are usually as the numbers 2, 3, 4, 5, 6, etc. These upper notes, harmonics or over-tones (see *harmonic*), blend with the fundamental note, and upon their number and relative intensity, consequently, the resultant combined effect upon the ear, or the quality of the note, depends. Sound-waves may, like light-waves, be reflected from an opposing surface (see *reflection*, *echo*, *resonance*); they may be refracted, or suffer a change of direction, in passing from one medium to another of different density; they may suffer diffraction: and they may also suffer interference, giving rise to the pulsations of sounds called *beats*. See *beat*[1], 7.

2. A particular quality or character of tone, producing a certain effect on the hearer, or suggesting a particular cause; tone; note: as, a joyful *sound;* a *sound* of woe.

Signifying nothing. *Shak.*, Macbeth, v. 5. 27.

6. Same as *signal*, 2. — **Anacamptic sounds.** See *anacamptic.* — **Blood-sounds,** in *auscultation*, anemic murmurs. — **Bronchial sound,** the normal bronchial breathing-sound. — **Cardiac sounds,** the heart-sounds. — **Characteristic sound.** See *characteristic letter*, under *characteristic.* — **Cogged breath-sound.** See *breath-sound.* — **Friction sound.** See *friction-sound.* — **Refraction of sound.** See *refraction.* — **Respiratory sounds.** See *respiratory.* — **To read by sound,** in *teleg.* See *read*[1].

=Syn. 1. *Noise*, *Sound*, *Tone*. *Noise* is that effect upon the ears which does not convey, and is not meant to convey, any meaning: as, the *noise* made by a falling chimney; street *noises*. *Sound* is a general word, covering *noise* and intelligible impressions upon the auditory nerves: as, the *sound* of cannon, of hoofs, of a trumpet, of prayer. *Tone* is *sound* regarded as having a definite place on the musical scale, or as modified by feeling or physical affections, or as being the distinctive quality of sound possessed by a person or thing permanently or temporarily: as, his *tones* were those of anger; a piano of peculiarly rich *tone*. For technical distinctions, see def. 1 above, *noise*, and *tone*.
